DEPARTMENT OF HIGHWAYS ONTARIO

MEMORANDUM

To: Mr. A.P. Watt,
Bridge Location Engineer,
Administration Building.

From: Mr. B.K. Glassford

Date: April 28th, 1964.

OUR FILE REF.

IN REPLY TO

Subject: A.P. 316-64-1
316-64-2

Attached are the reports, logs of holes and profiles for the diamond drill investigation of bedrock on the above work projects at Kingston and Wolfe Island.

The drilling was done under supervision of the Materials and Research geologist, Mr. O. Valkirs, of the Kingston regional office. The log of holes were completed by him and revised slightly at the Materials and Research laboratory. Sections of the investigational report were done by Mr. Valkirs, the remainder of the report was completed at the Toronto laboratory after examination and testing of the cores.

B.K. Glassford

B.K. Glassford,
Geologist.

PWStch

Mr. A.P. Watt,
Bridge Design Section,
Administration Building.

Mr. B.K. Glassford

April 22nd, 1964.

W.P. 316-64-1, Ferry Dock, Rogers Road East of Kingston,
District 8

W.P. 316-64-2, Ferry Dock, Knapp Point Wolfe Island,
District 8

Diamond drill core investigation work was carried out for
the above work projects from March 31st. to April 9th.

Three diamond drill cores of bedrock were taken at the
following points for W.P. 316-64-1.

| <u>D.D.H.</u> | <u>Station</u> | <u>Collar Elevation</u> | <u>Gradeline Elevation</u> | <u>Depth of Hole</u> |
|---------------|---------------------------------|-----------------------------|--------------------------------|--------------------------|
| 1 | 18 + 32 7' W. of centre line | 250.4' | 234' | 26' 3" |
| 2 | 16 + 51 2' W. of centre line | 272.2' | 258' | 27' 11" |
| 3 | 12 + 80 on centre line | 306.3' | 280' | 29' 2" |

DDH #1

Bedrock in this drill hole consists mainly of medium hard to hard limestone of a grey to dark grey colour, aphanitic in texture, with some shale partings and soft limestone in transitional sections. The bedding in the upper 10 feet is thin to thick bedded (3" to 18"). The structure of the rock is stylolitic in appearance. Below the 10 foot mark and to the 22 foot horizon there appears to be an increase in argillaceous content of the limestone. Rock from 0' to 10' should make suitable cribbing fill material for the deck, while larger blocks from the thicker beds near the top should provide material for the causeway framework. Rock from 10' to the bottom of the hole appears highly argillaceous and clayey, and hence undesirable for crib work, but should make causeway fill material if used above water level.

cont'd

DRILL #2

Bedrock here is a limestone, dark grey colour, medium hard to soft, aphanitic in texture with shale partings. There appears to be some lost core in the drilling, probably due to shaly material. Rock from below the overburden to approximately 13 feet appears suitable for rock cribbing material. From 13 feet to 22 feet the material is undesirable and should not be used for either crib fill or causeway fill. From 22 feet to the bottom of the hole (27 feet) the rock appears acceptable for crib fill material.

DRILL #1

Bedrock here is a medium hard to soft, dark grey fine grained limestone with shale partings and clayey lime sections. Below the 1 foot of overburden the first 3 feet of rock would be acceptable for crib fill material. Between 3 feet and 7 feet the rock is not acceptable for crib work, but could be used for causeway fill material above water levels. Rock from 7 feet to 21 feet appears acceptable for crib fill material. Between 21 feet and 24 feet there is a bad section of soft clayey limestone which is unacceptable and should not be used for either crib or causeway fill material. From 24 feet to the bottom of the hole (29' 2") the rock appears acceptable for crib fill use.

In summary of the above descriptions; rock material indicated as acceptable could be used for crib fill and/or causeway breakwater core fill material. Rock described as not being acceptable for crib material aggregate for the most part should be avoided and wasted. Sections as indicated could possibly be used for core rock in the causeway if used above the water levels. Further breakdown and disintegration of the rock used should occur with resulting settlement in the cribs and causeway. Future fill replacement will be required at a later date.

In appraising the rock in these cores from this site two main considerations were kept in mind.

1. Rock material was not a high grade, excellent, hard type limestone. Its physical conditions were appraised good or bad for the intended use.
2. The intended use was a fill material for both above and below water levels.

cont'd.....

From these descriptions and from the plotted profile of the bore holes it appears that a specific selective mining or quarrying operation would be necessary to obtain material from the excavation for each intended use. This would call for a close supervision of the contractor's drilling, blasting and excavation procedures.

It is further suggested that the outer limits of the breakwater below and above water levels be fortified with an armour type rock. A rock of this type is available on the site a few hundred feet east of the proposed right of way. This rock is an extremely hard wearing and durable quartzite, which would add greatly to the physical resistance to wave and water action on the exposed perimeter of the breakwater causeway.

Knapp's Point, Wolfe Island

One diamond drill core of bedrock was taken at Knapp's Point, Wolfe Island, for I.P. 316-64-2.

| <u>D.D.H.</u> | <u>Station</u> | <u>Collar Elevation</u> | <u>Boreline Elevation</u> | <u>Depth of Hole</u> |
|---------------|----------------|-------------------------|---------------------------|----------------------|
| 4 | 70 + 35 | 245.0' | | 16' 11" |

DDH #4

There was no overburden at this drill site. Bedrock here consists of a medium hard, dark grey, aphanitic limestone with narrow transitional bedding of argillaceous and clayey layers. There are some shale partings present. Rock from the top of the bore hole to 16' 11" (bottom) appears suitable for crib fill and causeway breakwater fill material.

Additional investigation was carried out for possible sites of bedrock which could be suitable as fill in timber cribs as well as for causeway. No diamond drilling was done in the areas described below.

A knoll of bedrock located close to Sta. 62+00 and west of it contains no fly shaly or clayey limestone with few 1/2 - 2 ft. layers of medium to hard limestone and few 1 - 5 ft. layers of shale or clay. A cross section at Sta. 7 + 0 and 2 + 0 ft. west of it is as follows:

- 6-
- 0 - 5' Shale or claystone platy and very soft.
 - 5 - 6' Limestone, shaly, thin bedded to platy soft.
 - 6 - 6½' Shale or claystone, platy and very soft.
 - 6½ - 8½' Limestone, medium hard to hard, dark grey, medium thick beds.
 - 8½ - 9' Shale or claystone, platy and soft.
 - 9 - 12' Limestone, medium hard to hard, few shale seams and partings, thick bedded.

One sample (64-LR-1014) was taken at the outcrop on river's shore from the depth of 0 to 12 feet. All material taken in sample has been exposed to weathering for a considerable time period. Depth of excavation will be limited from 12 to 15 feet by the water level in St. Lawrence River. Excavation below water level could be hindered by seepage zones of water in bedrock. The layer of bedrock below 12' is the same as the top of D.D.H. 4 was placed.

A large knoll of bedrock around Sta. 60+00 appears to be very similar to the knoll described above (e.g. knoll west of Sta. 68+00). This area is covered by overburden, but the few outcrops indicate that the upper 0 - 5' contain mostly shale or shaly limestone and below it 5 to 10 feet there are 1 - 2 foot layers of medium hard to hard limestone with few shale partings or seams (1 - 6" thick) and few (6" - 12" thick) layers of shaly limestone.

A small quarry located approximately 750' east of Sta. 4+00 has a small 8' face and in cross-section it consists of:

- 0 - 2' limestone, medium hard to soft
- 2 - 5' shale, platy and soft
- 5 - 8' limestone, in parts shaly, medium thick bedded with shale partings and few shale seams, medium hard to hard.

A quarry located west of D.H.C. Patrol Yard on north side of Hwy. 96, approximately 2½ miles from Sta. 00+20 has a 15 - 20 foot face and it contains mostly soft shaly limestone with few layers of shale and few 1 - 2 foot layers of medium hard to hard limestone. Bedrock in this quarry appears to be non-uniform in horizontal extent as well. A small section located in northeast corner of quarry contains a better quality stone than the rest of quarry.

cont'd

A fairly large quarry located approximately one mile west of the Village of Wolfe Island and approximately 4 miles from the job site has a 20 - 25 foot face. The upper 10' in this quarry contain mostly shaly limestone with few thin layers of shale and medium hard limestone. Below 10' to 18' the bedrock is mostly medium hard to hard limestone in parts slightly shaly. Below 18', the bedrock is shaly limestone to shale.

There appears to be certain sections of limestone in the above described quarries on Wolfe Island that would be suitable for crib fill material. Mining of this material would probably involve selective quarrying methods, with wasting of the unacceptable shaly and claystone rock horizons.

B.M. Glassford,
Geologist.

DEPARTMENT OF HIGHWAYS ONTARIO

MEMORANDUM

To: Mr. A.P. Watt,
Bridge Design Engineer,
Administration building.

From: Mr. B.K. Glassford

Date: April 24th, 1964.

Our File Ref.

In Reply To

Subject: W.P. 316-64-1, Ferry Dock at Rogers Road, East of Kingston,
District #

W.P. 316-64-2, Ferry Dock at Knapp's Point, Wolfe Island,
District #

The following are answers to your questions to Mr. A. J. Stermac, Principal Foundation Engineer, contained in your letter to him of April 1st.

W.P. 316-64-1

1. If the rock is suitable for use in timber cribs?

Certain beds of the limestone between specific footings levels appears suitable for timber crib fill material. These beds are described in the descriptions of each diamond drill hole and are drawn in on the grade profile map. Other sections of the limestone appear unacceptable for crib fill rock.

2. If the rock is suitable for use in a rock fill causeway?

Certain sections of the limestone appear acceptable for causeway fill rock, some sections for use above the water level only. These sections are described in the diamond drill hole report and are also marked on the grade profile map.

3. What the probable size of the rock breakage will be?

The probable size of rock breakage will be from a maximum of 2 feet to approximately 15 ft. below the

4. Characteristics of the rock in regard to under water excavation?

Breakage of the limestone at the under water section should be in the maximum to average sizes (as described in) for the first 10 feet below the ground elevation level at shore-line (see description of 50M /1 and profile of same bore hole on the grade line profile C-20-32). Below this footage breakage sizes should be smaller with considerable more fines. This breakage appraisal will of course depend on the powder load and the blast hole pattern and method used by the contractor.

5. The bearing strength of the rock?

The crushing strength of the rock below the dock cribbing and on which the crib timbers rest should be in excess for the load which will be placed upon it. This crushing strength would be considered at 6 to 10 tons per square foot.

Map. 114-44

1. If the rock is suitable for use in timber crib fill?

Rock from the dock slip area would be suitable for crib fill material. Adjacent material in the rock outcrops appears unsuitable for rock crib fill material, but would make core fill above water levels for breakwater causeway fill material.

2. If rock in the quarry 1 mile from the dock site is suitable for crib fill material?

Certain sections of the limestone quarry face appear suitable for crib fill rock. These bedding levels would have to be indicated to the contractor by the geologist.

3. Probable size of rock breakage?

Maximum breakage size would be 14 feet, with the average size 6 to 8 inches and with approximately 20% fines, or 20% below the 1 inch screen size.

-3-

4. Characteristics of the rock in regard to under water excavation?

Breakage of the limestone at the under water section should be in the maximum to average sizes (as described in 3). This breakage appraisal will of course depend on the powder load and the blast hole pattern and method used by the contractor.

5. Bearing value of the rock?

The crushing strength of the rock below the dock cribbing and on which the cribbing rests should be in excess for the loading which will be placed upon it. The crushing strength would be considered at 8 to 10 tons per square foot.
