Attention: Mr. B. N. Medicky

Dear Sirs:

Re: Site Investigation  
Maryhill Bridge

Enclosed are four copies of our report of the findings encountered at the above mentioned site. Two soils testholes have been performed to determine the soil stratigraphy, the apparent bearing capacities (based on the standard penetration test) and water levels and/or water seepage zones.

The bridge crossing is on Waterloo Country Road No. 36 over Hopewell Creek, approximately 1 mile south of Maryhill, north-east of Kitchener. Testholes are located approximately 10 ft. behind the corners of the existing abutments at upstream side of the bridge, as indicated on the attached sketch.

A. SOIL DESCRIPTION

From ground level to ±5 ft. there is a loose bouldery fill used in the construction of the original bridge. Beneath this abutment backfill, the original river bottom deposits of layered brown plastic clay and loose peat exist to depths of 8 or 9 ft. from surface. Below the original loose river bottom

deposits, the soil is a grey brown layered silty fine sand, extending to about 18 ft. and 14 ft. from surface at holes 1 and 2 respectively. This sand is variably compact with "N" values ranging from 11 to 24 blows/ft., the more compact condition being found at the upper portion of the stratum at hole 1 only. The sand was considered to be saturated, with natural moisture contents ranging from 10 to 17%.

The terminal stratum underlying the "just compact" sand is a grey silty sand till which is dense to very dense, with "N" values ranging from 36 to more than 80. This till is only moist with natural moisture contents consistently only 7 or 8%. Testhole 1 was terminated at 31 ft. from surface and hole 2 was terminated at 21 ft. 6 inches from surface after encountering difficulties with a boulder interference with further sampling. The till appeared to be slightly more clayey at hole 2.

#### B. WATER CONDITIONS

The elevation of the water in the creek is 94.82. Depth of water found in hole 1 was at 5 ft. 6 inches or elevation 94.71. Hole 2 caved at 6 ft. 6 inches suggesting water at that level which is 93.42. Also, these figures reflect a water level approximately that of the creek.

#### C. CONCLUSIONS AND RECOMMENDATIONS

The abutments to the new bridge could be supported on spread footings placed into the upper surface of the grey brown silty fine sand at depths of about 10 ft. below existing grade. The footing bearing value should be limited to 1.0 tons/sq. ft.; the theoretical maximum settlement with this load application is 1 inch.

With a spread footing foundation design, it may be necessary to provide scour protection to the face of the abutments, since the sand stratum is regarded as easily disturbed or eroded if the creek velocity should increase sharply during spring flood. Any cut-off sheet piling should preferably penetrate to the underlying dense till; alternatively, rip rap placed on the creek bottom in front of the abutments may provide adequate protection against scour developing under the front edge of the abutments.

As an alternative foundation design, we recommend consideration to the use of a piled foundation, with the piles founded into the upper surface of the dense silty sand till stratum at depths of 14 ft. to 18 ft. below existing surface, i.e. at elevations ranging from 86.0 to 82.2. Bored caissons will encounter some difficulty in maintaining "open hole" through the sand stratum. Either driven tube piles, or Franki type displacement piles are considered most suitable. You may also wish to consider the use of timber piles, preferably creosoted or otherwise protected against eventual deterioration due to variation of water levels. Steel "H" piles may also be considered; such piles may extend somewhat further into the dense silty sand till before achieving an adequate set.

A water condition will develop in any excavation below approximately the existing creek water level, i.e. elevation 94.8 at the time of the field work. Thus, some dewatering will be necessary if spread footings, founded at elevation 90±, are adopted as the foundation design. Dewatering by pumping from the excavation bottom is likely to result in bottom disturbance and possibly "quicking" of the sand, and thus any dewatering must be carried out by pumping from outside the foundation area.

Yours very truly,

E. M. PETO ASSOCIATES LTD.

E. M. Peto, P.Eng.
