**PART 1: FACTUAL INFORMATION**

**1 INTRODUCTION**

This report presents the factual information obtained from a foundation investigation at the proposed locations of high embankments and swamps along the proposed Highway 11 mainline alignment extending from Highway 124 to Muskoka Road (Strong Township, Mainline Sta. 19+875 to 21+150). The report also addresses high embankments and swamp crossings on the adjacent portions of Highway 124 and Muskoka Road as well as the ramps for the Highway 124 Interchange.

The purpose of the investigation was to explore the subsurface conditions at sites where embankments higher than 6 m or swamp crossings are proposed, and based on the data obtained, to provide a borehole location plan, borehole logs, stratigraphic profile and cross-sections and a written description of the subsurface conditions.

Thurber carried out the investigation as a sub-consultant to Marshall Macklin Monaghan (MMM), under the Ministry of Transportation Ontario (MTO) Agreement Number 5005-A-000188.

**2 SITE DESCRIPTION**

This report addresses the portion of the proposed Highway 11 Mainline extending approximately 1.3 km from Muskoka Road intersection with Hwy 11(at the south limit) to the north end at the proposed interchange with Highway 124. The proposed alignment is located in Strong Township and generally runs parallel to the existing Highway 11 in the southern portion and becomes new four-lane section in the northerly parts.

The site is located in the physiographic area known as the Laurentian Highlands of the Canadian Shield which generally consists of undulating terrain with uplands areas comprised of bedrock outcrop or overburden soils comprised of granular outwash or basal till of variable thickness. Swamps or lakes are commonly present in the low-lying areas. The southern portion of the

proposed alignment is located on the west side of a 30 m high upland area. The Highway 124 interchange at the north end of the project is located on relatively level swampy terrain east of a second 30 m high upland area.

Drainage in the surrounding areas is typically poor and is comprised of swamps and small streams. The majority of the study area drains generally north and then eastwards into Bernard Lake, located approximately 1 km east of Highway 11. The west edge of the study area (Highway 124) drains generally westwards into a tributary of Stirling Creek.

The majority of the land along this section of the proposed alignment is undeveloped forested land with occasional open swamps or pastures. The junctions of Muskoka Road and Highway 124 have light commercial and residential development which increases in density near the south boundary of the Town of Sunridge.

The proposed Highway 11 alignment and interchange crosses several wet, swampy areas where high fills are proposed. These areas are summarized below:

- Muskoka Road, Sta 9+275 to 9+550
- Highway 124, Sta 9+100 to 9+225
- West side of proposed Interchange, Hwy 11 Sta. 20+300 to 20+550  
(E-S Ramp)

### 3 SITE INVESTIGATION AND FIELD TESTING

The site investigation and field testing for this portion of the project were carried out between Sept 12, 2002 and May 27, 2004. The site investigation consisted of drilling and sampling a total of 162 boreholes and 22 Dynamic Cone Penetration Tests (DCPT) to depths ranging from 0 to 15 m. A summary of boreholes drilled at the various portions of the project are summarized below:

|                              | Boreholes | DCPT |
|------------------------------|-----------|------|
| Highway 11 Mainline          | 58        | 3    |
| Hwy 11/124 Interchange Ramps | 61        | 11   |
| Hwy 124                      | 23        | 5    |
| Muskoka Road                 | 20        | 3    |

The median centreline location and stations were surveyed and staked in the field by Marshall Macklin Monaghan (MMM) prior to commencing drilling operations. The borehole and DCPT locations were established in the field by Thurber personnel based on the staked median centreline or approach ramp centreline as applicable. The boreholes are labelled based on the individual station and offset for each alignment. Property access, site preparation and utility clearances were carried out by Thurber prior to any drilling being carried out. The locations of the boreholes are

shown on the attached "Borehole Locations and Soil Strata Drawings" found in Appendices A through E. The site plans, topography and proposed height of embankments shown on the drawings were provided by MMM, dated May 2004.

The drilling, sampling and in-situ testing operations were carried out by All-Terrain Drilling of Waterloo, Ontario and George Downing Estate Drilling of Port Hawkesbury, Ontario. The boreholes were advanced by CME 75 drill rigs mounted on Nodwell tracked carriers using hollow stem and solid stem auger techniques. Disturbed samples were obtained at selected intervals using a split spoon sampler in conjunction with Standard Penetration Testing (SPT) in most overburden soils. Where cohesive layers exhibiting lower strength were encountered, in-situ vane shear tests and thin-walled tube samples were collected.

Dynamic Cone Penetration Tests (DCPT) were carried out at the toe of fill location (alternating intermediate stations) to obtain a continuous profile in the upper portion of the deposit. The DCPT tests were carried out by continuous penetration of a 50 mm diameter steel cone (60 degree) driven by a standard SPT hammer. The DCPT profiles are shown on the borehole logs in the Appendices A through E.

The drilling and sampling operations were supervised on a full time basis by a member of Thurber's technical staff. The supervisor logged the boreholes and the recovered disturbed and undisturbed samples and processed the samples for transport back to Thurber's Oakville laboratory.

Upon completion of drilling and sampling, standpipe piezometers were installed in select boreholes. Piezometer construction generally utilized of 19 mm diameter Schedule 40 PVC pipe with 1.5 m long slotted tips installed near the bottom of the boreholes. The piezometers installations were backfilled with a sand filter pack extending from the bottom of the hole to at least 0.3 m above the top of the screen and bentonite clay seals (holeplug) placed above the filter sand and at just beneath the ground surface. The interval between the bentonite seals was backfilled with cuttings and bentonite. Boreholes without a piezometer were backfilled using bentonite and drill cuttings.

The Record of Borehole logs, "Borehole Locations and Soil Strata" drawings, and laboratory test result summaries are included in each of the separate appendices as shown below:

|            |   |
|------------|---|
| Appendix A | Hwy 11 Mainline, Strong Township, Sta. 19+875 to 20+525 |
| Appendix B | Hwy 11 Mainline, Strong Township, Sta. 20+525 to 21+150 |
| Appendix C | Highway 124/Highway 11 Interchange Ramps                |
| Appendix D | Highway 124   |
| Appendix E | Muskoka Road Connection                                 |

#### 4 LABORATORY TESTING

All recovered soil samples were returned to Thurber's laboratory where they were subjected to visual identification and to natural moisture content determination. The results of this testing are shown on the Record of Borehole sheets in the Appendices as described in the preceding section.

Selected samples were subjected to gradation analysis (sieve test) and Atterberg Limit testing. A one-dimensional consolidation test was also carried out on one sample.

#### 5 DESCRIPTION OF SUBSURFACE CONDITIONS

Reference is made to the Record of Borehole sheets in the Appendices. Details of the soil stratigraphy encountered are presented in the Appendices A through E. A general description of the stratigraphy at each of the swamps and where high fills are proposed is given in the following sections.

##### 5.1 Highway 11 Mainline Embankment, Sta. 19+875 to 20+525

The Highway 11 Mainline between Sta. 19+875 and 20+525 will consist of a new four-lane section supported by an embankment which is generally 6 to 10 m in height. The anticipated footprint of the proposed fill is about 80 to 110 m in width.

The soils encountered in the boreholes drilled along this portion of the alignment generally consist of topsoil (organic silt) or peat layer overlying a mixture of silt and fine sand which in turn overlies a unit of silty clay to clayey silt. The above sequence is interrupted occasionally by a layer of discontinuous sand found either above or below the silt and sand unit. The preceding sequence, or the upper part of it, was found to overlay discontinuous sand a very hard layer, which resulted in auger refusal (inferred bedrock or cobbles and boulders).

##### Topsoil, Organic Silt and Peat

A layer of organic silt or topsoil was encountered in most borehole locations at the ground surface south of approximately Sta. 20+325. A surface peat layer was encountered at the ground surface between approximately Sta. 20+325 and Sta. 20+500.

The organic silt and topsoil layer is described as silt, organic, trace to some sand, with occasional rootlets and occasional wood fibres or as sandy topsoil. The deposit was typically dark brown in colour with occasional iron oxide staining. The thickness encountered in the borehole varied from 50 mm to 800 mm. The SPT N-values in this deposit varied from 1 to 7 indicating very loose to loose conditions. The moisture content of disturbed samples collected from the organic silt varied from 42 to 102%.

The peat deposit is described as peat, fibrous, silty, trace sand, with occasional rootlets and wood fibres. The colour was dark brown. The thickness encountered at the borehole

locations varied from 0.2 to 1.5 m. The SPT N-values varied from 2 to 3 indicating very loose conditions. The moisture content of the disturbed samples recovered from the peat deposit varied from 106 to 856 % by weight.

### **Upper Sand**

In localized areas, such as from Sta. 20+375 to 20+425 left of median centreline, an upper sand deposit was encountered underlying the topsoil or peat layers. The thickness of this unit encountered in the boreholes was 0.4 to 0.9 m.

This unit is generally described as fine grained sand, trace to some silt, trace gravel and occasional cobbles. Trace of organics and rootlets was noted in some samples. The deposit is brown in colour with occasional oxide staining. The SPT N-values ranged from 6 to more than 100 indicating loose to very dense conditions.

### **Silty Sand, Silt and fine Sand, Sandy Silt**

At most locations the surficial topsoil and peat layers or upper sand layer were underlain by a deposit containing a variable mixture of silt and fine sand. The composition of this unit was variable ranging from silty sand; sand and silt mixtures; sandy silt; through to silt some clay. The minor constituents noted in the samples included, occasional rootlets, trace gravel and occasional cobbles. The sand fraction was typically fine grained. The thickness of this deposit varies from 1.0 to 4.6 m.

The deposit was typically brown in colour with occasional oxide staining.

SPT N-values in this deposit range from 7 to 46 indicating a loose to dense condition. Some higher SPT N-values (>100/0.1m) were noted near the lower boundary of this unit where refusal conditions were encountered.

The moisture content of disturbed samples collected from this unit varied from 16 to 24%.

The results of grain size analyses conducted on samples from this unit are summarized in Figures A1through A4 in Appendix A and on the Record of Borehole sheets.

### **Silty Clay to Clayey Silt**

From Sta. 20+300 to 20+20+500, cohesive silty clay to clayey silt deposit was encountered underlying the silt and sand unit described above. This deposit is described as silty clay to clayey silt, trace sand. The thickness of silty clay and clayey silt encountered in the boreholes varied from 0.8 to 5.7 m. Auger refusal was generally encountered at the lower boundary of this unit indicating that it is underlain by boulders or bedrock.

The deposit is typically brown to grey in colour with occasional oxide staining.

The SPT N-values recorded in this unit range from 7 to 16, indicating a stiff to very stiff condition.

The moisture content of disturbed samples recovered from this unit varied from 23 to 37%. The Atterberg limit tests carried out in this deposit resulted in ranged liquid limits of 22 to 29% and plastic indices of 5 to 9%. The fraction of clay-sized particles (<2 µm) encountered in the samples ranged from 22 to 34% by weight. The portion of sand sizes was less than 10%.

The results of the laboratory testing are summarized in Figures A6 and A8 in Appendix A.

### **Groundwater**

Observations of groundwater conditions during drilling and measurements of water levels in piezometers indicate that the groundwater table is generally near the ground surface (Elev 350 m to 352 m) in the low-lying swamp areas, and 1 to 2 m below the ground surface (Elev 353 m to 363 m) in the upland areas. The groundwater levels are expected to vary seasonally and with heavy precipitation events.

### **5.2 Highway 11 Mainline Embankment, Sta. 20+525 to 21+200**

The Highway 11 Mainline between Sta. 20+525 and Sta. 20+200 will consist of a new four-lane section supported by an embankment which is generally 5 to 11 m in height. South of approximately Sta. 20+775 and north of approximately Sta. 20+950, the embankment height reduces to 6 m or less. The anticipated footprint of the proposed fill is about 80 to 90 m in width.

The soils encountered in the boreholes along this portion of the alignment generally consisted of a sandy topsoil or peat layer overlying a sand deposit. The sand layer in turn overlies bedrock or a deposit comprised of silt to sandy silt or a silt and sand mixture. Locally thin layers of clayey silt was encountered beneath the topsoil near BH20+550 L18.75, underlying the sandy silt deposit at Sta. 20+550 R21.75 and underlying the sand unit at BH20+925 L18.75.

### **Topsoil and Peat**

A layer of topsoil or peat was encountered in most borehole locations. The thickness of this deposit varied from 0.2 to 0.6 m.

The topsoil layer is described as sandy topsoil, with occasional rootlets and occasional wood fragments. The deposit was typically dark brown in colour with occasional iron oxide staining. The SPT N-values in this deposit varied from 4 to 5 indicating very loose conditions. The moisture content of disturbed samples collected from the topsoil layer varied from 23 to 25%.

The peat deposit was encountered locally from 20+895 to 21+000 and is described as peat, fibrous. The colour was dark brown to black.

### Sand

At most locations, a sand deposit was encountered underlying the topsoil or peat layers described above. The thickness of the sand unit as encountered in the boreholes was 0.4 to 3.8 m.

This unit is generally described as fine grained sand, trace silt to silty, trace gravel with occasional cobbles and gravelly zones. Trace to some organics were noted in some samples. The deposit is brown or reddish-brown in colour with occasional oxide staining. The SPT N-values ranged from 6 to more than 100 indicating loose to very dense conditions.

The moisture content of the disturbed samples varied from 10 to 24%.

The results of the gradation analyses in Figure B1 and B2 in Appendix B.

### Clayey Silt

In localized areas between Sta. 20+550 and Sta. 20+625 and at 20+925, a cohesive clayey silt deposit was encountered underlying the sand unit described above. This deposit is described as clayey silt, trace to some sand with occasional sand, silt and clay lenses or laminations. The thickness of the clayey silt encountered in the boreholes varied from 0.8 to 1.8 m.

The deposit is typically grey in colour.

The SPT N-values recorded in this unit range from 4 to 30, indicating a soft to very stiff condition.

The moisture content of disturbed samples recovered from this unit varied from 22 to 36%. The Atterberg limit tests carried out in this deposit resulted in liquid limits ranging from 23 to 25% and plastic indices of 4 to 6% indicating low plasticity. The fraction of clay-sized particles (<2 µm) encountered in the samples ranged from 18 to 23% by weight. The portion of sand sizes in the samples was typically less than 5%.

The results of the laboratory testing are summarized in Figure B3 in Appendix B.

### Silt to Sandy Silt

From Sta. 20+525 to 20+600 and locally at Sta. 2+800, 20+950 and 20+970, a layer of silt to sandy silt was encountered underlying the sand unit described above. This deposit is generally non-cohesive to slightly cohesive and is described in the borehole records as silt, some sand or as sandy silt, some clay. Occasional silty clay laminations were noted in some boreholes (20+598 R18). The thickness of silt and sandy silt encountered in the boreholes varied from 0.3 to 1.6 m.

The deposit is typically brown to grey in colour with occasional oxide staining.

The SPT N-values recorded in this unit range from 6 to 49, indicating loose to dense conditions. At locations where the deposit was considered to be cohesive, the SPT N-values ranged from 6 to 8 indicating firm consistency.

The moisture content of disturbed samples recovered from this unit varied from 18 to 28%. The Atterberg limit tests carried out in this deposit resulted in liquid limits ranging from 22 to 25% and plastic indices of 4 to 5% indicating low plasticity. The fraction of clay-sized particles (<2 µm) encountered in the samples ranged from 7 to 15% by weight. The portion of sand sizes was less than 4 to 38%.

The results of the laboratory testing are summarized in Figures B4 to B5 in Appendix B.

### **Silty Sand to Silt and Sand**

From Sta. 20+950 to 21+200, the stratigraphic layers described above were underlain by a deposit containing a mixture of silt and sand grading to silty sand. The composition of this unit was variable ranging from sand and silt mixtures to silty sand trace clay. The deposit was stratified with thin silty sand layers. The sand fraction was typically fine grained. The thickness of this deposit varies from 0.9 to greater than 4.4 m. The lower boundary of this unit was not encountered in the boreholes.

The deposit was typically brown in colour with grey silty interbeds.

SPT N-values in this deposit range from 11 to 30 indicating a compact condition.

The moisture content of disturbed samples collected from this unit varied from 19 to 27%.

The results of grain size analyses conducted on samples from this unit are summarized in Figures B5, B6 and B7 in Appendix B and on the Record of Borehole sheets.

### **Groundwater**

Observations of groundwater conditions during drilling and measurements of water levels in piezometer at 21+150 R18.75 (Elev 352.1 m) indicate that the groundwater table is generally near the ground surface (Elev 350 m to 352 m) in the low-lying swamp areas, and 1 to 2 m below the ground surface (Elev 350 m to 352 m) in the upland areas. The groundwater levels are expected to vary seasonally and with heavy precipitation events.

## **5.3 Highway 11/ Highway 124 Interchange Ramps**

Seven new ramps are proposed for the interchange of Highway 11 and Highway 124 and will consist of several intersecting embankments with different heights. The proposed embankment section will consist of an approximately 8 m wide road allowance supported by fill with a footprint varying from about 32 m to 60 m in width, depending on the embankment height. Subsurface information was collected where proposed embankment

heights exceeded 6 m at the proposed embankment centreline and toe locations. A list of the interchange ramps investigated is provided below:

N-E Ramp  
N-EW Ramp  
E-S Ramp  
S-S Ramp  
W-S Ramp  
W-N Ramp  
E-N Ramp

The soils encountered in the boreholes along the various interchange ramps generally consisted of a discontinuous topsoil or peat layer overlying a silt and sand deposit. The silt and sand layer in turn overlies a deposit of cohesive clayey silt to silty clay. A lower sand unit was encountered underlying the cohesive deposit. Most of the boreholes and DCP tests encountered auger or cone refusal at the base of the lower sand unit indicating the presence of boulders or bedrock. The depth of the overburden soils was variable generally ranging from 2 m to 13 m below the ground surface.

#### **Topsoil and Peat**

A surficial layer of topsoil or peat was encountered at most borehole locations. The topsoil was typically encountered on the upland areas and the peat in the wet, low-lying areas. At the borehole locations, the thickness of the topsoil layer varied from 0.05 m to 0.6 m and the thickness of the peat varied from 0.3 to 1.7 m.

The topsoil layer is described as sandy or silty topsoil, with occasional rootlets and occasional wood fibres. The deposit was typically dark brown or brown in colour. The SPT N-values in this deposit varied from 2 to 15 indicating very loose to compact conditions. The moisture content of disturbed samples collected from the topsoil layer varied from 22 to 164%.

The peat deposit was encountered locally from 20+895 to 21+000 and is described as peat, fibrous with occasional layers of silty sand. The colour was dark brown to black. The moisture content of disturbed samples varied from 85% to 448%.

#### **Sand, Silt and fine Sand, Sandy Silt**

At most locations the surficial topsoil and peat layers were underlain by a deposit containing a variable mixture of non-cohesive silt and fine sand. The composition of this unit ranges sand trace to some silt; sand and silt mixtures; sandy silt; through to silt trace to some sand. The sand fraction was typically fine grained. The deposit generally becomes finer grained with increasing depth. The minor constituents noted in the samples included,

occasional rootlets, trace gravel and occasional cobbles. The thickness of this deposit varies from 0.8 to 5.3 m.

The deposit was typically brown in colour with occasional grey silt and clay laminations and oxide staining.

SPT N-values in this deposit range from 3 to 66 indicating a loose to very dense condition. Some higher SPT N-values ( $>100/0.1\text{m}$ ) were noted where cobbles were encountered or near the lower boundary of this unit where refusal conditions were met.

The moisture content of disturbed samples collected from this unit varied from 8 to 32%.

The results of grain size analyses conducted on samples from this unit are summarized in Figures C1through C4 in Appendix C and on the Record of Borehole sheets.

### **Clayey Silt to Silty Clay**

Beneath most of the proposed interchange ramps, except for the N-W Ramp and south of Sta. 20+600 on the N-E ramp, a cohesive clayey silt to silty clay deposit was encountered underlying the silt and sand unit described above. The cohesive deposit is generally described as clayey silt to silty clay, trace sand, but varies to silt, some clay trace sand to sandy. The deposit has frequent sand seams, and silt or clay lenses or laminations. The thickness of the clayey silt to silty clay encountered in the boreholes varied from 0.7 to 11 m.

The deposit is typically grey in colour, with occasional brown areas noted.

The SPT N-values recorded in this unit range from 1 to 24, indicating a soft to very stiff condition. Vane shear test resulted in measured shear strengths of 36 kPa to more than 100 kPa. The sensitivity of the cohesive deposits, based on remolded vane shear measurements, varied from 2 to 7, indicating low sensitivity.

The moisture content of disturbed samples recovered from this unit varied from 22 to 58%. The Atterberg limit tests carried out in this deposit resulted in ranged liquid limits of 22 to 32% and plastic indices of 4 to 13% indicating low plasticity. The fraction of clay-sized particles ( $<2 \mu\text{m}$ ) encountered in the samples ranged from 9 to 36% by weight. The portion of sand sizes in the samples was typically less than 12%, with a maximum sand content of 23% in one sample.

The results of the laboratory testing are summarized in Figures C5 to C16, in Appendix C.

### **Lower Sand**

In some areas near the western edge of the interchange (N-E and E-S ramps), a layer of sand was encountered underlying the cohesive clayey silt to silty clay unit described above. The sand deposit is described in the borehole records as sand trace to some silt, trace to some gravel and as gravelly or silty sand. Occasional cobbles or boulders were also noted

in the boreholes. The thickness of the lower sand layer encountered in the boreholes varied from 0.4 to 2.0 m.

The deposit is typically brown in colour.

The SPT N-values recorded in this unit generally range from 12 to more than 100, indicating compact to very dense conditions. The higher SPT N-values (>100/0.1m) were noted where cobbles, boulders or the underlying bedrock were encountered.

The moisture content of disturbed samples recovered from this unit varied from 18 to 22%.

The results of the laboratory testing for this unit are summarized in Figures C3 in Appendix C.

### **Groundwater**

Observations of groundwater and soil moisture conditions during drilling indicate that the groundwater table is generally near the ground surface (Elev 350 m to 352 m) in the low-lying swamp areas, and 1 to 3 m below the ground surface (Elev 350 m to 353 m) in the upland areas. The groundwater levels are expected to vary seasonally and with heavy precipitation events.

### **5.4 Highway 124 Embankments**

A realignment of the existing Highway 124 is proposed west and east of the new interchange with Highway 11. The new alignment of Highway 124 will have three separate areas where embankment fill higher than 6 m or swamp crossings are proposed. These areas are:

|                                 |                                   |
|---------------------------------|-----------------------------------|
| Hwy 124, Sta. 9+100 to 9+240:   | 3 - 4 m high embankment on swamp  |
| Hwy 124, Sta. 9+760 to 9+940:   | 7 – 18 m high embankment on swamp |
| Hwy 124, Sta. 10+050 to 10+150: | 6 – 10 m high embankment          |

The soils encountered in the boreholes advanced within the three areas identified above generally consisted of a discontinuous topsoil or peat layer overlying a sandy silt to sand deposit. From Sta. 9+100 to 9+240, where the bedrock was relatively shallow (<2 m), the sand directly overlies the bedrock. However, at the two more eastern locations, the depth of bedrock increases to 15 m maximum, and the silty sand to sand deposit was found to overlay a layer of sandy silt supported by an underlying layer of silty clay unit. A lower sand to sand and gravel unit was encountered underlying the cohesive silty clay deposit. Most of the boreholes and DCP tests encountered auger or cone refusal at the base of the lower sand unit indicating the presence of boulders or bedrock.

Standing water was encountered up to 300 mm above the ground surface during drilling at the lower elevations from Sta. 9+100 to 9+240.

### **Topsoil and Peat**

A surficial layer of topsoil or peat was encountered at most borehole locations. The topsoil was typically encountered on the upland areas and the peat in the wet, low-lying areas. At the borehole locations, the thickness of the topsoil layer varied from 0.1 m to 0.5 m and the thickness of the peat varied from 0.1 to 0.9 m.

The topsoil layer is described as sandy topsoil, with occasional rootlets and occasional wood fibres. The deposit was typically dark brown in colour.

The peat deposit is described as peat, fibrous with occasional rootlets. The colour was dark brown to black. The moisture content of disturbed samples varied from 119% to 385%.

### **Sand to Silty Sand**

At most locations along Highway 124, the surficial topsoil or peat layers (where present) were underlain by a variable deposit comprised of cohesionless sand to sandy silt. The composition of this unit generally ranges from sand trace to some silt; to silty sand. Less frequently areas of sand and silt mixtures or sandy silt were encountered. The minor constituents noted in the samples included: peat inclusions, occasional rootlets, wood-fibres, trace gravel. The thickness of this deposit varies from 0.1 to 2.8 m.

The deposit was typically brown in colour.

Most of the SPT N-values in this deposit range from 2 to 50 indicating a very loose to dense condition. Some higher SPT N-values (>100/0.1m) were noted near the lower boundary of this unit where refusal conditions on boulders or bedrock were encountered.

The moisture content of disturbed samples collected from this unit generally varied from 15 % to 22%. Extreme values up to 82% were encountered where peat inclusion or other organics were noted in the deposit.

The results of grain size analyses conducted on samples from this unit are summarized in Figures D1 and D2 in Appendix D and on the Record of Borehole sheets.

### **Silt and Sand to Sandy Silt**

At Hwy 124, Sta. 9+760 to 9+940, where the depth to bedrock increases to more than 12 m a cohesionless silt and sand to sandy silt unit was encountered underlying the sand to silty sand deposit described in the preceding section. The deposit is generally described as sand and silt varying to sandy silt or to silt some clay, trace to some sand. Occasional clay or sand seams and layers were noted in this unit. The thickness of the Silt and Sand unit encountered in the boreholes varied from 0.7 to 4.3 m.

The deposit is typically brown in colour, with occasional grey areas noted.

The SPT N-values recorded in this unit range from 4 to 37, indicating very loose to dense condition.

The moisture content of disturbed samples recovered from this unit varied from 20 to 28%.

The results of the laboratory testing are summarized in Figure D3 in Appendix D.

### Silty Clay

A silty clay deposit was encountered underlying the silt and sand to sandy silt unit described above. The silty clay deposit varies from clayey silt to silty clay, or a mixture of silt and clay. The deposit contains trace to some sand. The deposit has frequent sand and silt seams, lenses or laminations. The thickness of the clayey silt to silty clay encountered in the boreholes varied from 2.7 to 10.0 m.

The deposit is typically grey in colour, with rare brown zones noted in the upper part of the deposit.

The SPT N-values recorded in this unit range from 1 to 6, but occasionally up to 16.. Vane shear test resulted in measured shear strengths of 8 kPa to more than 100 kPa indicating very soft to very stiff conditions. The sensitivity of the cohesive deposits, based on remolded vane shear measurements, varied from 2 to 7, indicating low sensitivity.

The moisture content of disturbed samples recovered from this unit varied from 18 to 48%. The Atterberg limit tests carried out in this deposit resulted in ranged liquid limits of 22 to 30% and plastic indices of 4 to 10% indicating low plasticity. The fraction of clay-sized particles (<2 µm) encountered in the samples ranged from 13 to 40% by weight. The portion of sand sizes in the samples was typically less than 10%.

A one-dimensional consolidation test was carried out on an undisturbed sample from Borehole 9+899 L1.5 at 8.8 m depth. The results of the test are summarized in Table 5.1. Detailed test results are included in Appendix D.

TABLE 5.1: CONSOLIDATION TEST SUMMARY

| Borehole   | Sample depth (m) | In situ s' (kPa) | w (%) | e <sub>o</sub> | Pc' (kPa) | OCR | Cc   | Cr   |

The results of the laboratory testing are summarized in Figures D4 to D9, in Appendix D.

### **Lower Sand or Sand and Gravel**

In most areas along Highway 124, a layer of sand or sand and gravel was encountered beneath the units described above and directly overlying auger refusal conditions indicating bedrock or boulders. The sand deposit is described in the borehole records as sand trace to some silt, trace to some gravel or as sand and gravel. Occasional cobbles were also noted in the boreholes. The thickness of the lower sand layer encountered in the boreholes varied from 0.1 to 1.2 m.

The deposit is typically brown in colour.

The SPT N-values recorded in this unit generally range from 39 to greater than 100, indicating dense to very dense conditions. The higher SPT N-values (>70/0.2m) were generally noted where cobbles or the underlying bedrock were encountered.

The moisture content of disturbed samples recovered from this unit varied from 8 to 22%.

### **Groundwater**

Observations of groundwater and soil moisture conditions during drilling indicate that the groundwater table is generally near or 0.3 m above the ground surface (Elev 370 m to 370.5 m) in the swamp areas between Stations 9+100 and 9+250 along Highway 124.

West of the proposed Highway 124/ 11 underpass the groundwater table was encountered 1 to 2 m below the ground surface (Elev 350 m to 363 m) in the upland areas and near or 1 m above the ground surface (Elev 350 m to 351 m) in the low-lying areas.

East of the proposed underpass, the groundwater table was encountered approximately 0.9 m below the ground surface (Elev 354 m).

The groundwater levels are expected to vary seasonally and with heavy precipitation events.

### **5.5 Muskoka Road Embankments**

A new Muskoka Road Connection is proposed west of the proposed Highway 11 four-lane alignment and south of the interchange with Highway 124. The new alignment of Muskoka Road Connection will have two separate areas where embankment fill higher than 6 m or swamp crossings are proposed. These areas are:

- |                                  |                                     |
|----------------------------------|-------------------------------------|
| Muskoka Rd, Sta. 9+250 to 9+500: | 6 – 10.5 m high embankment on swamp |
| Muskoka Rd, Sta. 9+625 to 9+825: | 6 – 15 m high embankment            |

The soils encountered in the boreholes advanced within the southern swamp area identified above (Sta. 9+250 to 9+500) generally consisted of a surficial topsoil or peat layer overlying an upper sand layer which in turn was underlain by a slightly cohesive deposit of

silt with some clay. North of approximately Sta. 9+400, refusal conditions were encountered beneath the cohesive silt at 3.5 to 6.5 m depth. However, south of this location a deposit of cohesionless sandy silt to silty sand was encountered underlying the cohesive silt layer. Occasional zones of cohesionless sandy silt to silty sand materials were also encountered within the cohesive silt. An underlying layer of sand and gravel was encountered locally beneath the silt and sand layers near the south limits of the proposed embankment (Sta. 9+250).

The soils encountered beneath the proposed northern embankment (Sta. 9+625 to 9+825) generally consisted of the following sequence:

- Fill
- Peat or topsoil
- Silt and Sand mixtures (silty sand to sandy silt)
- Silt some clay to Clayey silt (cohesive)
- Lower sand, silty or gravelly

Not all the layers noted above were encountered in each borehole. The fill soils for example were only present near the existing access road, and some of the units were not continuous across the proposed embankment foundation area. A generalized description of the soil units is provided in the following sections.

### **Fill**

Fill was encountered near the Access Road at Muskoka Rd Sta. 9+722. The fill was comprised of sand and gravel over silty sand with organics. The thickness of the fill was 1.2 m. SPT N-values ranged from 4 to 5 indicating the materials were very loose to loose.

### **Topsoil and Peat**

A surficial layer of topsoil or peat was encountered at most borehole locations. The topsoil was typically encountered on the upland areas and the peat in the wet, low-lying areas. At the borehole locations, the thickness of the topsoil layer varied from 0.1 m to 0.6 m and the thickness of the peat varied from 0.2 to 1.9 m.

The topsoil layer is described as sandy topsoil, with occasional rootlets and occasional wood fibres. The deposit was typically dark brown in colour.

The peat deposit is described as peat, fibrous with occasional rootlets. The colour was dark brown to black. The moisture content of disturbed samples varied from 58% to 552%.

### **Upper Sand Deposit**

The upper sand layer was only encountered at the southern swamp area and is described as sand, trace silt, trace gravel. The sand was typically fine to medium grained. The thickness of this deposit varied from 0.8 m to 2.0 m. The colour was brown or grey. SPT N-values

ranged from 10 to 24 indicating compact conditions. The moisture content of disturbed samples varied from 15 to 22%.

### **Silt and Sand Mixture**

In the northern embankment foundation area, a non-cohesive deposit of silt and sand in varying proportions was encountered. The composition of this unit generally ranges from sandy silt to silty sand and includes mixtures of fine grained sand and silt. Occasional silt and clay seams were noted at some locations. The minor constituents noted in the samples included: occasional rootlets, peat inclusions, trace to some gravel or trace clay. The thickness of this deposit varies from 0.3 to 2.8 m.

The deposit was typically brown, reddish brown or grey in colour with occasional oxide staining.

The SPT N-values in this deposit ranged from 7 to 49 indicating loose to compact conditions.

The moisture content of disturbed samples collected from this unit generally varied from 10 % to 22%. Extreme values up to 94% were encountered where peat inclusion or organics were noted in the deposit.

The results of grain size analyses conducted on samples from this unit are summarized in Figures E1 through E4 in Appendix E and on the Record of Borehole sheets.

### **Silt some clay to Clayey Silt**

Beneath portions of both the south and northern embankment locations, a cohesive silt deposit was encountered underlying the Upper Sand or the Silt and Sand units described above. This cohesive deposit varies from silt some clay to clayey silt. The deposit contains trace to some sand and occasional cobbles. Sand, silt and clay seams, lenses or laminations were noted in the north of Sta. 9+700. The thickness of the silt some clay to clayey silt unit encountered in the boreholes varied from 0.3 to 3.1 m.

The deposit is typically brown or grey in colour, with occasional oxide staining.

The SPT N-values recorded in this unit generally range from 9 to 33, indicating generally stiff to hard conditions.

The moisture content of disturbed samples recovered from this unit varied from 13 to 29%. The Atterberg limit tests carried out in this deposit resulted in ranged liquid limits of 19 to 23% and plastic indices of 4 % indicating very low plasticity. The fraction of clay-sized particles (<2  $\mu\text{m}$ ) encountered in the samples ranged from 13 to 29% by weight. The portion of sand sizes in the samples was typically less than 15%.

The results of the laboratory testing are summarized in Figures E5 to E6 and E8, in Appendix E.

### **Lower Sand or Sand and Gravel**

A layer of sand or sand and gravel was encountered beneath the units described above and directly overlying auger refusal conditions indicating bedrock or boulders. The sand deposit is described in the borehole records as silty sand, trace to some gravel, as gravelly sand, or as sand and gravel trace to some silt. Occasional cobbles and boulders were also noted in some boreholes. The thickness of the lower sand layer encountered in the boreholes varied from 0.8 to 3.9 m.

The deposit is typically brown in colour.

The SPT N-values recorded in this unit generally range from 27 to more than 100, indicating compact to very dense conditions. The higher SPT N-values (>100/0.05m) were generally noted where cobbles, boulder or the underlying bedrock were encountered.

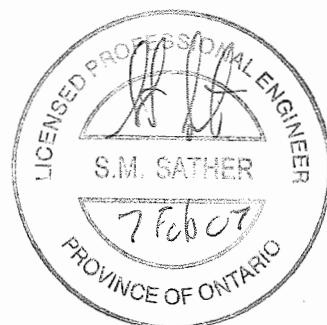

The moisture content of disturbed samples recovered from this unit varied from 8 to 35%.

### **Groundwater**

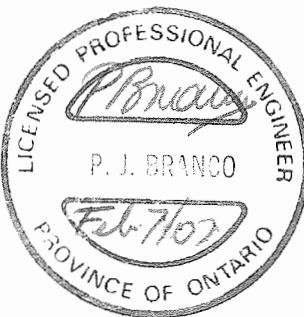

Observations of groundwater and soil moisture conditions during drilling and in the standpipe piezometers indicate that the groundwater table is generally near the ground surface. Depth to groundwater table measured in the piezometers varied from 0.3 to 0.64 m below the surface following completion of drilling. Some boreholes were drilled from frozen swamps where up to 500 mm of surface water was encountered above the ground surface.

**PART 2: ENGINEERING DISCUSSION AND RECOMMENDATIONS**

**6 GENERAL**

This report presents interpretation of the geotechnical data in the factual report and presents preliminary foundation design recommendations where embankment heights exceed 6 m or swamp crossings have been proposed.

The discussion and preliminary recommendations presented in this report are based on our understanding of the project and on the factual data obtained in the course of the investigation.

**7 ENGINEERING ANALYSIS METHODOLOGY**

**7.1 General**

The project information, including plan and profile of the proposed alignments dated May 2004, utilized in the engineering analysis was provided by MMM. For the purpose of analysis and reporting the proposed embankments and swamp crossings along the proposed Highway 11 alignment, interchange ramps and other highway alignments have been treated separately. A summary of the various segments is provided below:

- Hwy 11 Mainline, Strong Township, Sta. 19+875 to 20+525
- Hwy 11 Mainline, Strong Township, Sta. 20+525 to 21+150
- Highway 124/Highway 11 Interchange Ramps
- Highway 124
- Muskoka Road

The major factors governing foundation design of the proposed embankments include:

- Proposed embankment geometry (height, slope angle, footprint, etc)
- Embankment material type (earthfill, Select Subgrade Material -SSM or rockfill)

- Extent and thickness of surficial organic soils
- Thickness and engineering properties of underlying mineral soils
- Depth to competent layer (bedrock or dense gravel)
- Groundwater conditions

The geotechnical analysis summarized in this report includes assessment of the global stability of different embankment geometries and material types for both short and long term conditions. Assessment of immediate and long term settlement magnitudes and rates was also carried out. The analyses were based on the soil profiles and properties encountered at various locations. The location of the design sections and soil properties were selected for the more unfavourable locations.

The design of embankment stability and settlement are based on conventional factors of safety and selection of design parameters obtained from careful review of field and laboratory test results and engineering experience. The level of field and laboratory testing carried out for this project is expected to yield a reasonable level of reliability for the design. The design reliability could be improved by carrying out additional field investigation and laboratory testing (such as CPT). However, this additional work is not part of the current scope of work.

## 7.2 Design Options

Several design alternatives were considered in carrying out the embankment design, including:

- Subexcavation of peat and organics versus overland construction
- Provision for berms, geosynthetic reinforcement or flattening of slopes to improve global stability
- Staged construction to improve short term stability
- Preloading/surcharge to reduce long term settlements
- Wick drains to accelerate dissipation of excess pore pressure

A comparison of the advantages, disadvantages and relative cost is presented in the Table 7.1. The table presents design options for addressing stability, short term and long term settlements. For comparison purposes, the estimated relative unit costs presented in the table are based on generalized design parameters for a 60 m wide by 18.3 m high embankment section founded on a 12 m deep deposit of soft silty clay, similar to Hwy 124, near Sta.9+920.

The preferred design options are presented in Section 8. The recommended embankment design options are based on an anticipated construction schedule of 2 years. The final grading and pavement construction is expected to occur after this time.

### 7.3 Stability and Settlement Analyses

The stability analyses were carried out using limit equilibrium methods by the commercially available slope stability program “GSLOPE” developed by Mitre Software Inc. Bishop’s modified method of slices was used in the analyses. Based on consideration of the risk involved and past experience with highway embankment design and monitoring of embankment performance, a Factor of Safety (FS) of 1.3 is considered appropriate to maintain embankment stability and control deformations during construction. A FS of 1.5 is recommended for assessment of global embankment stability for long term conditions.

Immediate foundation settlements due to compression of the non-cohesive soils have been estimated based on the methods described in the CHBDC, 2000 Commentary Section C6.6.3.6.

The estimated consolidation settlement magnitude and time to achieve the majority of this consolidation (90%) was calculated based on Terzaghi’s one-dimensional vertical consolidation formulation combined with calculation of stresses in a two-dimensional elastic half-space as described in the CHBDC Commentary Section 6.6. The parameters used in the settlement analysis were determined by correlation of soil moisture and strength data to numerous laboratory tests from similar geologic units in the central Ontario region.

### 7.4 Seismic Considerations

The following seismic parameters have been used in design

|                                     |      |
|-------------------------------------|------|
| ▪ Velocity Related Seismic Zone     | 1    |
| ▪ Zonal Velocity Ratio              | 0.05 |
| ▪ Acceleration Related Seismic Zone | 2    |
| ▪ Zonal Acceleration Ratio          | 0.1  |

In accordance with the CHBDC, the soil profile type at this site is classified as Type III (more than 9 m of soft to medium stiff clay), which according to Table 4.4.6.1 of the CHBDC is associated with a Site Coefficient of 1.5. A peak horizontal ground acceleration (PHA) of 0.17g, where g is the acceleration due to gravity, has therefore been used in this analysis. This PHA value corresponds to a probability of exceedance of 10% in 50 years.

#### **7.4.1 Stability**

Stability of the embankments under seismic loading was assessed by carrying out a pseudo-static analysis using the parameters noted above. The pseudo-static analysis considers the application of the PHA to the soil mass on a non-softening foundation to assess the embankment stability. This assumption is considered reasonable given the subsurface conditions encountered in the site investigation. The analysis was carried out for embankments constructed from rockfill or from Select Subgrade Material (SSM). A summary of the results of each analysis is included in Appendix F.

The embankment stability analyses indicate that the Factor of Safety under short term seismic loads will range from  $FS = 1.1$  to  $1.2$ . These results indicate an acceptable margin of stability under seismic loading conditions.

#### **7.4.2 Liquefaction Potential**

Several of the proposed embankments will be constructed on relatively thin ( $<2$  m thick) loose to compact cohesionless layers overlying cohesive deposits. The water-table at the time of the field investigation was generally within or below the cohesionless soils. Based on the SPT N-values, partially saturated condition and the shallow depth of the cohesionless deposits, the likelihood of liquefaction of the foundation soils during the design seismic event is considered low. Some local liquefaction may occur during a seismic event resulting in local toe failure or minor settlement of the embankment, but this is expected to be readily repairable.

## **8 EMBANKMENT DESIGN**

### **8.1 General**

The generalized subsurface conditions and proposed embankment configurations for the various ramps, alignments and sections, are summarized in Table 8.1. Six representative areas were selected for detailed analysis based on the depth of compressible soils and areas exhibiting low shear strength. The areas selected for analysis are shown in Figure 1 following the text of this report.

Assessment of stability and settlement for embankments lower than 6 m height is beyond the scope of this report and is not included in this assessment.

The subsurface conditions vary from shallow cohesionless deposits providing relatively good stability and low foundation settlements, to deeper deposits of soft to firm cohesive clay where greater settlements and lower FS of global stability are expected. The groundwater table is typically at the ground surface where the deeper clay deposits are

encountered and 1 to 3 m below the surface in the upland areas. A summary of the soil model and the engineering parameters used in the analysis is included in Table 8.2.

## 8.2 Comparison of Foundation Design Options

A comparison of advantages, disadvantages and relative costs for various design options is presented in Table 7.1. The foundation design and construction issues related to embankment settlement and stability are presented in Table 8.3 along with the recommendations for the preferred design options.

A brief summary of the results of the analysis and the embankment design recommendations are described below:

### Hwy 124 (9+865 to 9+950)

A 20 m high embankment (including surcharge) is proposed and is to be founded on 10 m of firm, compressible cohesive soils. Design issues at this location include potential instability, short term settlement and long term foundation settlement. The preferred design measures recommended to address these issues consist of berms, staged construction, preloading/ surcharging, wick drains and monitoring of instrumentation.

The recommended berm sizes are based on the relative height of the proposed embankment and the depth of soil encountered. The berms are designed to provide a minimum Factor of Safety of 1.3 at each construction stage, for undrained loading conditions associated with expected construction rates. The assumption of undrained loading is considered reasonable given the limited plan area of the berms and embankments. Reduction of berm sizes may be possible if restrictions are placed on construction rates and partially drained conditions are allowed to develop during construction. This type of construction would require instrumentation and monitoring of excess pore pressure and displacements during construction. Development of these design options is outside of the current project scope.

### Muskoka Road (9+885 to 9+960)

The subsurface conditions encountered at centerline of the Muskoka Connection 9+885 to 9+960 consist of an approximately 6.5 m thickness of silty sand with interbedded stiff silty clay. Settlement of the roadway is not expected to be a factor in design for this section. However, the thickness of soft cohesive soil increases significantly towards the east, and at the location of the east embankment toe, the borehole information indicates that soft, cohesive deposits extend to at least 10 m depth. Analysis indicates that for the proposed 14 m high embankment height, short term stability will require provision for berms and staged construction in the design. The recommendations are discussed further in the following sections.

Hwy 11 Mainline (20+400 to 20+500)

The subsurface conditions encountered in the foundation for the proposed Hwy 11 mainline embankment comprise a surficial peat layer overlying compact silt and stiff to very stiff silty clay to more than 7 m depth. Aside from removal of the peat layer detailed in the following section, the foundation conditions encountered do not require specialized design recommendations related to stability and settlement of the proposed 8 m high embankment.

### **8.3 Peat and Topsoil Removal**

It is standard procedure in MTO projects to subexcavate peat deposits from within the embankment footprint if the underlying mineral soil will be encountered within 6 m of the ground surface. The foundation is then backfilled with rock or granular fill. For peat thickness of less than 6 m, this method is an economical and efficient method of improving stability during construction and minimizing the potential for large post-construction settlements. Where the peat thickness is greater than 6 m, construction becomes more costly and overland construction with surcharging may then be the preferred option.

Within the project limits addressed in this report, the depth of peat and organic soils is generally less than 2 m thick. It is therefore recommended that all peat and organic soils, where present be subexcavated from within the proposed fill footprint. The foundation area should be backfilled with rock or granular backfill as described in the following section. Placement of coarse rockfill material is recommended where standing water is encountered.

Table 8.4 provides a summary of the anticipated depth of subexcavation for peat and topsoil removal along the proposed alignments. The depth of stripping is based on the thickness of organics noted at the borehole locations. Stripping depth may vary from that noted in the table between the borehole locations.

In the stability and settlement analyses summarized below it has been assumed that the organic and peat layers have been removed and replaced with granular backfill as appropriate.

### **8.4 Stability Analysis**

The input parameters and soil model used in the stability analyses, including soil stratigraphy, properties, piezometric pressures, and embankment geometry, are summarized in Figures F1 through F14 in Appendix F following the text of the report. The stability analyses were only carried out where embankment heights exceed 6 m from the original ground surface.

Separate analyses were carried out for both earth fill embankments and rockfill embankments for short term (undrained), long term (effective stress) and seismic conditions. The analyses used the following variables:

- |                         |                 |
|-------------------------|-----------------|
| ▪ Earth fill embankment | slopes 2H:1V    |
| ▪ Rock fill embankment  | slopes 1.25H:1V |
| ▪ Height of surcharge   | 2 m             |

The results of the stability analysis for all other swamp areas where embankment height exceeds 6 m resulted in FS greater than 1.3 for short term conditions and greater than 1.5 for long term conditions. Stability analysis under pseudo-static seismic loading indicates a Factor of Safety exceeding 1.1. A summary of results of the stability analyses is provided in Table F-1 in Appendix F.

The results of the analyses indicate that stability will be acceptable (FS greater than 1.5) under long term drained conditions and under seismic loads (FS greater than 1.1). However, short term stability will not be adequate at several sites where high fills are proposed on soft foundation soils. These sites will require stabilizing measures to improve stability to acceptable levels as described below.

#### Hwy 124, 9+865 to 9+950

This portion of Highway 124 will require a 20.3 m high embankment (including 2 m surcharge) founded on loose silt and clay extending to 14.8 m depth. The lower 9 m of the soil profile is comprised of cohesive, firm to stiff, clayey silt. The analysis indicates a FS<1 under undrained conditions for this configuration. Construction in two stages and addition of berms are therefore required to allow construction up to the required embankment height with FS=1.3. To reduce the required berm sizes, the stability analysis allows for strength gain within the foundation following the application of the first construction stage. Instrumentation and monitoring of the excess pore pressures will be required to confirm loading conditions and control start of placement of the second construction stage. Details of berm placement and size are summarized in Table 8.5 following the text of the report.

#### E-S Ramp, 20+630 to 20+720

A 13.2 m high embankment (including 2 m surcharge) is proposed for this portion of the E-S ramp. The embankment will be founded on soft clayey silt extending to 7 m depth. The analysis indicates that FS =1 for undrained loading under these conditions. The addition of berms is required to allow construction without interruption to the required height with acceptable stability (FS=1.3).

E-N Ramp, 20+720 to 20+800

A 10 m high embankment is proposed for this location with no allowance for surcharge. The embankment will be founded on soft to firm clayey silt extending to 7.2 m depth. The analysis indicates  $FS < 1$  for undrained loading under these conditions. A berm is recommended on the right (east) side of the embankment to allow uninterrupted construction of the embankment to the design grade with  $FS > 1.3$ .

N-E Ramp, 20+700 to 20+790

An 11.4 m high embankment is proposed at this location, with no allowance for surcharge. The embankment will be founded on firm clayey silt extending to 7.1 m depth. The analysis indicates  $FS = 1$  for undrained loading under these conditions. A berm is recommended to allow uninterrupted construction of the embankment to the design grade.

Muskoka Road, 9+875 to 9+930

A 14 m high embankment is proposed at this location. Surcharge has not been included in the analysis as stiff soils near the road centreline are expected to result in foundation settlements of less than 50 mm. However, the thickness of soft cohesive soil increases significantly towards the east, at the location of the east embankment toe, where soft, cohesive deposits extend to at least 10 m depth. Analysis indicates that for the proposed embankment height, short term stability will not be adequate,  $FS < 1$ . Provision for berms and staged construction in the design will be required for stability under undrained conditions ( $F=1.3$ ). To keep the required berm sizes manageable, allowance for gain in foundation strength following the application of the first construction stage has been included in the analysis. Instrumentation and monitoring of the excess pore pressures will be required to confirm loading conditions and control the start of placement of the second construction stage. Details of berm placement and size are summarized in Table 8.5 following the text of the report.

#### **8.4.1 Berm Design Configuration**

Berm construction should be integrated with the overall construction of the embankments. The maximum slope of the berms should be as recommended for embankments of earthfill or rockfill materials as described above.

#### **8.4.2 Staged Construction**

Staged construction, instrumentation and monitoring will be required to complete the 18 m high embankments at:

- Highway 124, Sta. 9+950 to 9+865
- Muskoka Road, Sta. 9+885 to 9+960

Based on the stability calculations shown in Appendix F, the embankments at these locations can be raised to a maximum height of 12 m above the elevation of the embankment toe during the first stage of construction, provided that the berms are constructed first.

The second stage and the 2 m surcharge can be placed after monitoring of field instrumentation indicates that an acceptable level of the consolidation and strength has been achieved. The analysis requires that 90% of the consolidation be achieved for the first stage loading prior placement of the second stage. The estimated time for achieving 90% consolidation at each stage is provided in the following section.

The monitoring of settlements and pore pressures will require installation of instrumentation and monitoring of the instruments during construction. Design of the instrumentation and monitoring plans is outside of the scope of the current assignment. Target values for maximum excess pore pressure and values for confirming adequate dissipation will depend on the location and depth of the instruments and should be calculated in conjunction with the instrumentation design.

## 8.5 Settlement Analysis

### 8.5.1 Foundation Settlements

A settlement analysis was carried out using Terzaghi's one-dimensional consolidation theory with stresses calculated for two-dimensional embankment loading configurations. Input parameters were developed based on correlations between index and strength parameters measured at the site and correlated with oedometer tests carried out for this site and from adjacent areas of the Highway 11 project. The correlation of the compressibility and moisture content is included in Figure G-1.

The result of the settlement analyses are summarized in Table 8.6 following the text of the report. A detailed summary of the settlement analyses is included in Table G-1 in Appendix G.

A summary of the results of the settlement analysis is included below:

#### Hwy 124, 9+865 to 9+950

The settlement analysis for the proposed 18.3 m high embankment indicates a maximum primary settlement of 1060 mm. This settlement will apply near the centreline of the embankment. The estimated time for 90% of the primary settlement to occur considering that the embankment is constructed in two stages is 1.06 years. Long term settlement is estimated at 70 mm for a period of 30 years following construction. The settlement values are calculated for conditions where the greatest thickness of compressible soil was

encountered, near Sta. 9+913. A minimum 2 m surcharge is recommended for this embankment to reduce the post-construction settlement rate to less than 50 mm in 30 years.

To reduce the likelihood of disruption to the construction schedule, it is recommended that: vertical wick drains be installed at Hwy 124, Sta. 9+865 to 9+950. The design of wick drains is beyond the scope of this assignment.

#### E-S Ramp, 20+550 to 20+720

The foundation settlement analysis for the proposed 11.2 m high embankment indicates a maximum primary settlement of 300 mm, calculated at the embankment centreline. The estimate time for 90% of the primary settlement to occur is 2 to 3 months. Post construction settlement is estimated to be 60 mm over a 30 year period. A minimum 2 m surcharge is recommended to reduce the post construction settlement rate to less than 50 mm in 30 years.

#### Interchange Ramps

The estimated primary settlements calculated where compressible clay was encountered in the foundation for the E-N Ramp, Sta. 20+720 to 20+800 and the N-E Ramp, Sta. 20+700 to 20+760, are between 150 and 200 mm. The estimated time to achieve 90% consolidation is 2 to 3 months. Post construction settlement is estimated to be less than 50 mm in 30 years, and therefore surcharge is not required in these areas.

#### Muskoka Connection

Soils beneath the centerline of the Muskoka Connection were stiff to very stiff and highly overconsolidated. No significant foundation settlement is expected within the roadway.

#### Highway 11 Mainline

Compressible soil is present within the foundation of the Highway 11 mainline embankment between Sta. 0+400 and 20+450. The estimated primary foundation settlement associated with construction of the proposed 8.3 m high embankment is approximately 40 mm. Post construction settlement for a 30 year life is estimated to be 40 mm. Surcharge is not required for this area.

#### Design Settlement Rates

The rate of settlement due to primary consolidation in the field may vary from the theoretical estimates because of natural variation in soil properties, complex boundary conditions, and changes resulting from loss of structure in the clay deposit during loading. It is therefore recommended that the theoretical times for consolidation be increased by at least 100% to account for these variations for the purpose of estimating construction schedules.

The estimated long term foundation settlement rate resulting from secondary consolidation are considered manageable with conventional pavement maintenance schedules. However, surcharging of the embankment is recommended in all areas where total settlement will exceed 300 mm.

A minimum height of surcharge of 2 m is recommended. Additional height of surcharge is not expected to affect the long term settlement because the geometry of the fill would result in relatively small stress change in the foundation.

### **8.5.2 Embankment Settlements**

The estimated settlement of embankments constructed of rock fill or compacted earth fill will be 0.5% of the embankment height. This settlement is expected to occur within one to two years following completion of the embankments.

## **8.6 Embankment Construction**

### **8.6.1 Embankment Construction Over Swamps**

Construction of new embankments over swamp should be carried out in accordance with OPSS 209, "Construction Specification for Embankments Over Swamps", dated March 1998, and with specific reference to OPSD 203.010, "Embankments Over Swamps, New Construction".

For backfilling of subexcavation below the water-table or in swamps where surface water may be seasonally present above the ground surface, it is recommended that rock fill or coarse granular materials (OPSS Granular B Type II), be used as backfill. Placement of earthfill over rockfill should be avoided to prevent potential loss of material resulting from internal erosion.

### **8.6.2 Embankments**

Embankment construction should be carried out in accordance with OPSS 206, as amended by Special Provision "Amendment to OPSS 206, December 1993", dated November 2002. Earth fill may consist of granular materials and Select Subgrade Material (SSM) in compliance with Special Provision 110F13, "Amendment to OPSS 1010, March 1993".

Earth fill used for construction of embankments should be placed in regular lifts and compacted in accordance with OPSS 501. Benches, 2 m minimum in width, are required along slopes at 8 m maximum vertical intervals in earth and 6 m maximum vertical intervals in rock. The benches should extend the length of the embankment where the height exceeds 6 m.

Earth fill embankments slopes must be provided with erosion protection in accordance with Special Provision SP572SO1.

## 9 CONSTRUCTION CONCERNS

During construction, a qualified Geotechnical staff should be retained to observe activities related to embankment construction and advise the Contract Administrator on construction concerns or issues related to embankment stability or settlement.

Potential construction concerns to be highlighted are shown below, but the concerns are not necessarily limited to this list:

- Inspection and confirmation that all organics and peat materials within the proposed embankment footprints are sub-excavated and replaced with approved backfill.
- Instrumentation and monitoring of stability and settlement by qualified geotechnical staff is recommended where staged embankment construction has been recommended (Highway 124, Sta. 9+985 to 9+950) and Muskoka Road Connection (Sta.+885 to 9+960).
- The use of wick drains is recommended at Highway 124, Sta. 9+885 to 9+950 to increase the rate of consolidation. Detailed design of the wick drains is beyond the scope of the current assignment.

## SYMBOLS, ABBREVIATIONS AND TERMS USED ON RECORDS OF BOREHOLES

### 1. TEXTURAL CLASSIFICATION OF SOILS

| CLASSIFICATION | PARTICLE SIZE      | VISUAL IDENTIFICATION                               |
|----------------|--------------------|---|
| Boulders       | Greater than 200mm | same  |
| Cobbles        | 75 to 200mm        | same  |
| Gravel         | 4.75 to 75mm       | 5 to 75mm   |
| Sand           | 0.075 to 4.75mm    | Not visible particles to 5mm                        |
| Silt           | 0.002 to 0.075mm   | Non-plastic particles, not visible to the naked eye |
| Clay           | Less than 0.002mm  | Plastic particles, not visible to the naked eye     |

### 2. COARSE GRAIN SOIL DESCRIPTION (50% greater than 0.075mm)

| TERMINOLOGY                     | PROPORTION    |
|---------------------------------|---------------|
| Trace or Occasional             | Less than 10% |
| Some                            | 10 to 20%     |
| Adjective (e.g. silty or sandy) | 20 to 35%     |
| And (e.g. sand and gravel)      | 35 to 50%     |

### 3. TERMS DESCRIBING CONSISTENCY (COHESIVE SOILS ONLY)

| DESCRIPTIVE TERM | UNDRAINED SHEAR STRENGTH (kPa) | APPROXIMATE SPT <sup>(1)</sup> 'N' VALUE |
|------------------|--------------------------------|--|
| Very Soft        | 12 or less                     | Less than 2                              |
| Soft             | 12 to 25                       | 2 to 4                                   |
| Firm             | 25 to 50                       | 4 to 8                                   |
| Stiff            | 50 to 100                      | 8 to 15                                  |
| Very Stiff       | 100 to 200                     | 15 to 30                                 |
| Hard             | Greater than 200               | Greater than 30                          |

NOTE: Hierarchy of Soil Strength Prediction

- 1) Laboratory Triaxial Testing
- 2) Field Insitu Vane Testing
- 3) Laboratory Vane Testing
- 4) SPT value
- 5) Pocket Penetrometer

### 4. TERMS DESCRIBING DENSITY (COHESIONLESS SOILS ONLY)

| DESCRIPTIVE TERM | SPT 'N' VALUE   |
|------------------|-----------------|
| Very Loose       | Less than 4     |
| Loose            | 4 to 10         |
| Compact          | 10 to 30        |
| Dense            | 30 to 50        |
| Very Dense       | Greater than 50 |

### 5. LEGEND FOR RECORDS OF BOREHOLES

|  |   |  |                            |
|--|---|--|----------------------------|
| SYMBOLS AND<br>ABBREVIATIONS<br>FOR<br>SAMPLE TYPE | SS Split Spoon Sample                     | WS Wash Sample                         | AS Auger (Grab) Sample     |
|  | TW Thin Wall Shelby Tube Sample           |  | TP Thin Wall Piston Sample |
|  | PH Sampler Advanced by Hydraulic Pressure | PM Sampler Advanced by Manual Pressure |                            |
|  | WH Sampler Advanced by Self Static Weight | RC Rock Core                           | SC Soil Core               |

Sensitivity =  $\frac{\text{Undisturbed Shear Strength}}{\text{Remoulded Shear Strength}}$

 Water Level  
 $C_{pen}$  Shear Strength Determination by Pocket Penetrometer

- (1) SPT 'N' Value Standard Penetration Test 'N' Value – refers to the number of blows from a 63.5kg hammer free falling a height of 0.76m to advance a standard 50 mm outside diameter split spoon sampler for 0.3 m depth into undisturbed ground.
- (2) DCPT Dynamic Cone Penetration Test – Continuous penetration of a 50 mm outside diameter, 60° conical steel point attached to "A" size rods driven by a 63.5 kg hammer free falling a height of 0.76 m. The resistance to cone penetration is the number of hammer blows required for each 0.3 m advance of the conical point into undisturbed ground.

UNIFIED SOILS CLASSIFICATION

| MAJOR DIVISIONS      |                                 | GROUP SYMBOL | TYPICAL DESCRIPTION   |
|----------------------|---------------------------------|--------------|---|
| COARSE GRAINED SOILS | GRAVEL AND GRAVELLY SOILS       | GW           | Well-graded gravels or gravel-sand mixtures, little or no fines.  |
|                      |                                 | GP           | Poorly-graded gravels or gravel-sand mixtures, little or no fines.  |
|                      |                                 | GM           | Silty gravels, gravel-sand-silt mixtures.   |
|                      |                                 | GC           | Clayey gravels, gravel-sand-clay mixtures.  |
|                      | SAND AND SANDY SOILS            | SW           | Well-graded sands or gravelly sands, little or no fines.  |
|                      |                                 | SP           | Poorly-graded sands or gravelly sands, little or no fines.  |
|                      |                                 | SM           | Silty sands, sand-silt mixtures.  |
|                      |                                 | SC           | Clayey sands, sand-clay mixtures.   |
| FINE GRAINED SOILS   | SILTS AND CLAYS<br>$W_L < 50\%$ | ML           | Inorganic silts and very fine sands, rock flour, silty or clayey fine sands or clayey silts with slight plasticity.     |
|                      |                                 | CL           | Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays.<br>( $W_L < 30\%$ ). |
|                      |                                 | CI           | Inorganic clays of medium plasticity, silty clays.<br>( $30\% < W_L < 50\%$ ).  |
|                      |                                 | OL           | Organic silts and organic silty-clays of low plasticity.  |
|                      | SILTS AND CLAYS<br>$W_L > 50\%$ | MH           | Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts.                                    |
|                      |                                 | CH           | Inorganic clays of high plasticity, fat clays.  |
|                      |                                 | OH           | Organic clays of medium to high plasticity, organic silts.  |
| HIGHLY ORGANIC SOILS |                                 | Pt           | Peat and other highly organic soils.  |
| CLAY SHALE           |                                 |              |   |
| SANDSTONE            |                                 |              |   |
| SILTSTONE            |                                 |              |   |
| CLAYSTONE            |                                 |              |   |
| COAL                 |                                 |              |   |

## EXPLANATION OF ROCK LOGGING TERMS

| <u>ROCK WEATHERING CLASSIFICATION</u> |  | <u>SYMBOLS</u>  |
|---------------------------------------|--|---|
| Fresh (FR)                            | No visible signs of weathering.  |   |
| Fresh Jointed (FJ)                    | Weathering limited to the surface of major discontinuities.  |  CLAYSTONE         |
| Slightly Weathered (SW)               | Penetrative weathering developed on open discontinuity surfaces, but only slight weathering of rock material.            |  SILTSTONE         |
| Moderately Weathered (MW)             | Weathering extends throughout the rock mass, but the rock material is not friable.                                       |  SANDSTONE         |
| Highly Weathered (HW)                 | Weathering extends throughout the rock mass and the rock is partly friable.  |  COAL              |
| Completely Weathered (CW)             | Rock is wholly decomposed and in a friable condition, but the rock texture and structure are preserved.                  |  Bedrock (general) |
| <u>DISCONTINUITY SPACING</u>          |  | <u>STRENGTH CLASSIFICATION</u>  |
| Bedding                               | Bedding Plane Spacing  | Rock Strength      Approximate Uniaxial Compressive Strength (MPa)      (psi)                         |
| Very thickly bedded                   | Greater than 2m  | Extremely Strong      Greater than 250      Greater than 36,000                                       |
| Thickly bedded                        | 0.6 to 2m  |   |
| Medium bedded                         | 0.2 to 0.6m  | Very Strong      100-250      15,000 to 36,000  |
| Thinly bedded                         | 60mm to 0.2m   |   |
| Very thinly bedded                    | 20 to 60mm   | Strong      50-100      7,500 to 15,000   |
| Laminated                             | 6 to 20mm  |   |
| Thinly Laminated                      | Less than 6mm  | Medium Strong      25.0 to 50.0      3,500 to 7,500   |
| <u>TERMS</u>                          |  | Field Estimation of Hardness*   |
| Total Core Recovery: (TCR)            | Core recovered as a percentage of total core run length.   | Weak      5.0 to 25.0      750 to 3,500   |
| Solid Core Recovery: (SCR)            | Percent Ratio of solid core of full cylindrical shape recovered. Expressed with respect to the total length of core run. | Very Weak      1.0 to 5.0      150 to 750   |
| Rock Quality Designation: (RQD)       | Total length of sound core recovered in pieces 0.1m in length or larger as a percentage of total core run length.        | Extremely Weak (Rock)      0.25 to 1.0      35 to 150   |
| Uniaxial Compressive Strength (UCS)   | Axial stress required to break the specimen  |   |
| Fracture Index: (FI)                  | Frequency of natural fractures per 0.3m of core run.   | Indented by thumbnail   |

RECORD OF BOREHOLE No S 19+875 L18.75 1 OF 1 METRIC

## NOTE

The boundaries between soil strata have been established only at Bore Hole locations. Between Bore Holes the boundaries are assumed from geological evidence.

# Consolidation Test Report

Page 1 of 3

CLIENT: MMM

FILE NUMBER: 19-1423-12

PROJECT: HWY 11, Burke's Falls - HWY 124

REPORT DATE: 20-Jan-05

---

TEST DATES: Jan 4, 2005 - Jan 19, 2005

SAMPLE: 9+899 L1.5, ST-4, 28'-29'8"ft.

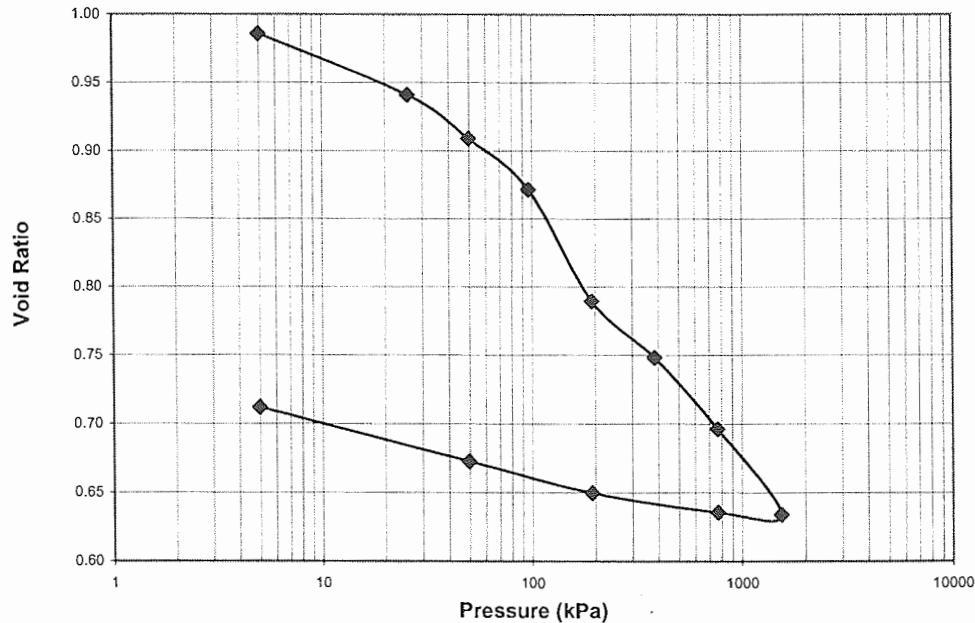

PROCEDURE: Tested in accordance with Standard Test Method for One-Dimensional Consolidation Properties of Soils, ASTM D 2435-90, method A

|                                | Start of Test | End of Test |
|--------------------------------|---------------|-------------|
| Wet Dens. (kg/m <sup>3</sup> ) | 1848.5        | 2061.0      |
| Dry Dens. (kg/m <sup>3</sup> ) | 1370.7        | 1600.8      |
| Moisture Cont. (%)             | 34.9          | 28.8        |
| Saturation(%)                  | 95.3          | 110.1       |
| Void Ratio                     | 1.006         | 0.718       |

Note:

A Specific Gravity of 2.75 was assumed for the void ratio and saturation calculations

Void Ratio vs Pressure

# Consolidation Test Report

HWY 11, Burke's Falls - HWY 124  
19-1423-12

Page 2 of 3  
9+899 L1.5, ST-4, 28'-29'8"ft.

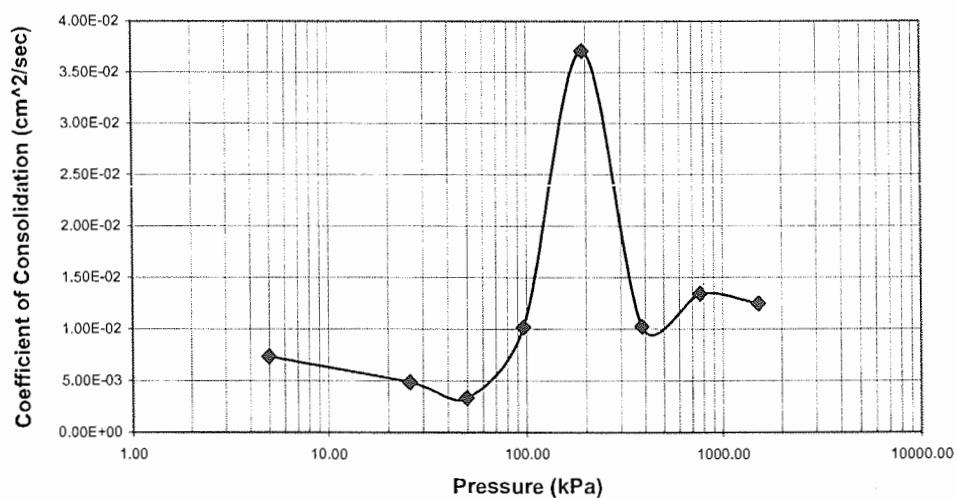

**TRIMMING:** The Specimen was manually trimmed to the size of consolidation ring, then mounted in a fixed ring consolidometer

**LOADING:** A seating load of 5 kPa was applied and the consolidometer was flooded with distilled water. Sample was monitored to ensure no swelling effect occurred before the start of the test. Subsequent loads were applied and the duration of each load step was 24 hours except the 4th and 6th loadings were 48 hours for Secondary Compression Calculations

**CALCULATIONS:** Coefficients of Consolidation were calculated by the square root time method.

| Pressure<br>(kPa) | Sa. Hgt.<br>(mm) | Corr. Hgt<br>(mm) | D90<br>(mm) | T90<br>(min) | Cv<br>(cm <sup>2</sup> /sec) | Void<br>Ratio | mv<br>(m <sup>2</sup> /kN) | k<br>(cm/s) |

## NOTE

The boundaries between soil strata have been established only at Bore Hole locations. Between Bore Holes the boundaries are assumed from geological evidence.
