PART 1: FACTUAL INFORMATION

1 INTRODUCTION

This report presents the factual findings obtained from a foundation investigation involving static pile load tests, piezocone testing and vane shear strength testing at the Pic River Bridge site on Highway 17 about 8 km east of Marathon.

The existing Pic River Bridge carries Highway 17 over the Pic River valley on a three-span steel truss structure with a total length of 178.3 m. The valley is underlain by a thick deposit of soft to stiff varved clay, which overlies a deep silt deposit exhibiting artesian groundwater pressures. The bridge piers and abutments are supported on steel H-piles (12 BP 53 / HP 310 x 79) driven into the clay deposit, locally into the underlying silt stratum at the west abutment.

During bridge construction in 1959, static pile load tests were conducted on several test piles to confirm that the design capacity derived by static analysis was achieved. The load test results indicated that the design capacity of the piles was not achieved, and that driving piles to greater depths in attempts to increase the capacity actually resulted in a capacity decrease.

To avoid the need for significant changes to the bridge design, electro-osmotic treatment was applied to the foundation clay at the west pier, east pier and east abutment in an effort to increase the pile capacity and reduce the potential for foundation settlement. Subsequent pile load tests on treated foundations indicated a gain in pile capacity through treatment, and this gain was sustained during additional load tests conducted in subsequent years, including the latest test in 1992.

The purpose of the current work program was to carry out another set of static pile load tests on selected piles at the east and west piers, confirm whether the gain in pile capacity has been maintained, conduct piezocone and vane testing adjacent to the test piles to assess the current

condition of the foundation clay, evaluate the current geotechnical resistance of the pile foundations, and provide foundation recommendations for rehabilitation (deck replacement) of the existing bridge.

This work was authorized by MTO Northwest Region under Assignment No. 6013-E-0012.

In the preparation of this report, reference has been made to the following selected reference reports from Geocres and published papers:

4. Paper entitled "First Application of Electro-Osmosis to Improve Friction Pile Capacity – Three Decades Later" by Victor Milligan, Golder Associates. Paper published in the 13th International Conference on Soil Mechanics and Foundation Engineering held in New Delhi, 1994.

2 SITE DESCRIPTION

The Pic River Bridge is located on Highway 17 approximately 8 km east of Marathon, Ontario. At present, the highway crosses the Pic River on a three-span through steel truss structure supported on two piers and two abutments. The span lengths are 48 m, 82.3 m and 48 m. The total length of the bridge is 178.3 m and the width is approximately 11.7 m. A snowmobile trail bridge exists to the north of the existing bridge.

The river channel at the bridge is approximately 67 m wide and 7.5 m deep. The river flows to the south and is relatively fast-flowing at this location. Rock fill erosion protection is visible above the river level in the lower parts of the approach embankments and valley slopes.

Photographs in Appendix A show the existing bridge structure and general nature of the site.

The river valley is underlain by an approximate 18 m thick deposit of soft to stiff varved clay, grading to stratified silt and then to silty fine sand at 70 to 80 m depth. The depth to bedrock is greater than 80 m and has not been determined. Artesian water pressure was encountered in the silt stratum.

3 INVESTIGATION PROCEDURES

3.1 Previous Investigation

A foundation investigation was carried out in April 2011 to determine the subsurface conditions along a proposed detour bridge alignment situated approximately 15 m to the south of the existing bridge. The fieldwork consisted of three boreholes drilled to depths of 26.5 to 46.3 m (Elev. 148.8 to 161.3) near the west pier, east pier and west abutment (designated Boreholes 11-01, 11-02 and 11-03, respectively). The Record of Borehole sheets, laboratory test results, and Borehole Locations and Soil Strata Drawing prepared for the initial detour alignment are presented in Appendix B.

In addition to the boreholes, piezocone penetration testing (CPTu) was carried out along the detour alignment, adjacent to each foundation unit. The locations of the piezocone tests are shown on the Borehole Locations and Soil Strata Drawing in Appendix B. The CPT plots provided by the piezocone contractor, ConeTec, are included in Appendix B.

The proposed detour was subsequently shifted away from this initial alignment.

3.2 Static Pile Load Tests

As part of the original foundation evaluation in 1959, a number of piles at each pier were isolated from the load bearing pile group by boxing out access portals in the pile cap to permit load testing during and after completion of electro-osmotic treatment of the foundations. A reaction beam was cast into the pile cap above each test pile to enable application of static loads on the piles. Subsequent to electro-osmotic treatment, static load testing of selected piles was carried out by MTO in 1961, 1968, 1971 and 1992 to confirm that the load capacity was sustained. The results of the load tests are available in MTO files and summarized in a paper published by V. Milligan (Reference No. 4).

The present scope of work involved static pile load tests conducted on three of the isolated piles, selected in consultation with MTO's Foundation Office:

- East Pier: Pile Nos. G-5 and E-16
- West Pier: Pile No E-2

The locations of the test piles within the pier pile groups are shown on Drawing 15-64-29-1 in Appendix C.

The static load test procedure was developed in discussion with MTO's Foundations Office and the procedure is attached in Appendix C. As indicated in the procedure, the piles were to be loaded to a maximum load of 800 kN and settlement of each pile was to be recorded at prescribed intervals under each load increment.

Geo-Foundations Contractors Inc. provided the pile load test set up, two 1,000 kN jacks, dial gauges and associated equipment. Thurber Engineering Ltd. recorded all load-settlement readings. The load test set-ups are shown in Geo-Foundations' Drawings G-13-24-SK1 and SK2 in Appendix C. Geo-Foundations provided the calibration charts for the jacks.

Photographs of the load test set-up are also presented in Appendix C. Four dial gauges were used for settlement measurement, one at each corner of the steel plate attached to the head of the pile. In addition, a fifth dial gauge was used to measure the deflection of the reaction beam. Further, a digital gauge was used to independently measure the settlements near one of the dial gauges.

3.3 Piezocone and Field Vane Testing

In addition to the pile load testing program, piezocone penetration testing and field vane testing were conducted within selected access portals in the pile cap. This testing was carried out to evaluate the current condition of the clay within the pile group and assess whether electro-osmosis had affected the clay between the piles in the group.

The piezocone penetration testing (CPT) was conducted at two locations within the east pier (CPT 13-F10-01 and 02 in pile access portal F10) and one location within the west pier (CPT 13-E16-03 in pile access portal E16). The locations are shown on Drawing 15-64-29-1 in Appendix C. The piezocones were pushed to a depth of 11.8 m.

One of the CPT tests at the east pier was pushed as close as possible to the pile (0.23 m from centre of the pile) while the second CPT test was pushed 0.56 m away from the pile in an effort to compare soil properties within and outside the zone of electro-osmotic treatment. At the west pier, the piezocone was pushed 0.3 m north of the test pile. Pore pressure dissipation tests were conducted at selected depths within the foundation clay.

Field vane testing employing the MTO N-vane was conducted at pile access portals F10 in the east pier and E16 in the west pier. The field vanes were conducted at approximately 0.75 m intervals within the foundation clay, to a maximum depth of 12 m.

4 RESULTS OF INVESTIGATION

4.1 Description of Subsurface Conditions

The subsurface conditions encountered in the boreholes previously drilled along the preliminary detour alignment generally consisted of 1.2 to 2.3 m of rock fill, overlying a 2.0 to 3.8 m thick deposit of loose sand/silt at the pier locations, underlain by varved silty clay. The clay deposit transitions to compact silt with clay bands below depths of approximately 17.6 to 27.0 m (Elev. 168.1 to 169.3 m). Details of the encountered soil stratigraphy are

presented on the Record of Borehole sheets and “Borehole Locations and Soil Strata” drawing in Appendix B.

In general, the silty clay deposit is soft to stiff, some 12.9 to 24.5 m thick, and contains 5 to 10 mm thick bands (varves) of silt. The undrained shear strength of the clay, measured by in situ vane testing, typically ranged from about 16 to 40 kPa in the upper 4.5 m of this deposit, and increased to 32 to 76 kPa below this level. Other properties of the clay were as follows:

- Moisture content: 30 to 60%
- Silt content: 28 to 34%; Clay content: 66 to 72%
- Silt content in silt interlayers: 58 to 72%; Clay content in silt interlayers: 28 to 42%
- Liquid Limit: 45 to 55; Plastic Limit: 22 to 24
- Intermediate to high plasticity (CI-CH).

The boundary between the silty clay and underlying silt deposit is transitional, with thinner clay and thicker silt bands occurring with increasing depth. The silt is loose to dense, typically compact, with moisture contents of 20 to 40%. The silt gradation includes 83 to 96% silt-size particles and 4 to 17% clay. The boreholes were terminated in the silt at depths of 26.5 to 46.3 m (Elev. 148.8 to 161.3 m).

The results of the piezocone penetration tests were generally consistent with the stratigraphy encountered in the boreholes. Locally at the west pier, the piezocone results identified an approximate 2 m thick layer of sand within the silty clay, between approximate depths of 7 to 9 m.

The water levels measured in the open boreholes upon completion and in the standpipe piezometers installed in the boreholes were as follows:

Table 4.1 – Measured Groundwater Levels

Borehole	Date	Measured Groundwater Level		Comment
		Depth (m)	Elevation	
11-01	May 1, 2011	-0.9*	188.7	In piezometer
	July 2, 2013	1.1	186.7	In piezometer
11-02	April 7, 2011	-0.8*	187.7	Upon completion
	July 2, 2013	1.6	185.3	In piezometer
11-03	May 1, 2011	0.0	195.1	In piezometer
	July 2, 2013	-0.7*	195.8	In piezometer

*denotes artesian condition

The source of the artesian water pressure is the silt deposit underlying the clay layer. A similar artesian condition was noted in the silt layer during the original 1958 investigation. V. Milligan in his paper reports a maximum artesian head of 6 m above existing ground at a depth of 80 m. At this depth and below, SPT blow counts were essentially zero due to piping in the borehole.

4.2 Results of Static Pile Load Tests

The results of the static pile load tests on Piles G-5 and E-16 at the east pier and Pile E-2 at the west pier are plotted on the load-settlement curves presented in Appendix D. The recorded settlement data used to prepare the plots are included in Appendix D.

Review of the pile load test data indicates the following:

1. The interpreted ultimate capacity of Piles G-5 and E-16 from the east pier ranges between about 550 and 600 kPa.
2. The load/deformation behaviour of the test piles at the east pier is essentially elastic below a load of 600 kN and the pile settlements are less than 5 mm. The settlement increased more rapidly with each load increment over 600 kN, reaching a maximum of 19 to 20 mm (indicating pile failure) at applied loads of approximately 690 and 750 kN before the load test was discontinued.
3. The load test for Pile E-2 at the west pier indicated that the pile did not reach failure at a loading of 900 kN and the pile settlement at this loading was in the order of 8 mm.
4. Each pile was unloaded and reloaded at one point during the load tests, and the resulting load-settlement behaviour remained essentially elastic.

4.3 Results of Piezocone and Field Vane Tests

The results of the piezocone penetration tests conducted at two locations within the east pier (CPT 13-F10-01 and 02) and one location within the west pier (CPT 13-E16-03) are presented in Appendix E. Plots showing the corrected tip resistance (q_t), sleeve friction (f_s), friction ratio (R_f), pore pressure (u), and soil behaviour type (SBT) interpreted from the test results are shown. The results of pore pressure dissipation tests conducted at selected depths are also provided in the appendix. The locations of the tests are shown on Drawing 15-64-29-1 in Appendix C.

The stratigraphy inferred from the piezocone tests typically consists of layered silts and sands to depths of about 5.6 to 6.8 m, underlain by silty clay to clayey silt with silt interbeds, extending to the exploration depth of 11.8 m.

The results of the field vane tests and interpreted subsurface stratigraphy are plotted on the Record of Borehole sheets (Boreholes 13-01 and 13-02) provided in Appendix E. The undrained shear strengths measured in the clay ranged from about 46 to 80 kPa at the east pier and from 58 to 80 kPa at the west pier.

5 MISCELLANEOUS

The static pile load tests were conducted by Geo-Foundations Contractors Inc. of Acton, Ontario. Thurber Engineering Ltd. supervised the load tests and recorded the load and settlement readings.

CPT testing was conducted by ConeTec Investigations Limited of Richmond Hill, Ontario. The drill rig used to push the cones and conduct vane testing was supplied by TBT Engineering of Thunder Bay, Ontario.

Mr. Mark Farrant, P. Eng. and Mr. Shahir Opiani of Thurber Engineering supervised the pile load tests, piezocene investigations and vane testing on a full-time basis. The field program was conducted under the direction of Mr. Jason Lee, P.Eng. of Thurber Engineering and Dr. P.K. Chatterji, P.Eng. of Thurber Engineering, a Designated Principal Contact for MTO Foundations Projects.

Interpretation of the data and preparation of the report were carried out by Mr. Jason Lee, P.Eng. The report was reviewed by Mr. Murray Anderson, P.Eng. and Dr. P.K. Chatterji, P.Eng., a Designated Principal Contact for MTO Foundations Projects.

PART 2: ENGINEERING DISCUSSION AND RECOMMENDATIONS

6 GENERAL

This report presents interpretation of the geotechnical data (static pile load tests, CPT and vane tests) presented in the factual report and presents geotechnical recommendations regarding the available geotechnical resistance and predicted settlement behaviour of the existing pile foundations supporting the Pic River Bridge.

The discussions and recommendations presented in this report are based on the factual data obtained at the east and west piers during the course of the current investigation, subsurface information obtained during a previous investigation along a preliminary detour alignment, and information presented in the documents referenced in the Foundation Investigation Report.

6.1 Existing Bridge Foundations

The existing bridge is a three-span through steel truss structure supported on two piers and two abutments. The end spans are 48.0 m in length and the centre span is 82.3 m long. The piers and abutments are each supported on a pile group system consisting of 12BP53 (HP 310 x 79) friction piles. Details of the foundation units are summarized in Table 6.1.

The piles were designed as friction piles driven into the thick deposit of soft to stiff varved clay underlying the site, locally into the underlying silt deposit at the west abutment. Electro-osmotic treatment was applied to the foundation clay at the west pier, east pier and east abutment, and a design pile capacity of 135 kN/pile was employed.

Table 6.1 – Existing Foundation Details

Foundation Unit	Number of Load-Bearing Piles	Driven Pile Length (m)	Pile Cap Dimensions (m x m)	Centre to Centre Pile Spacing (m)
East Abutment	33	17.1	3.5 x 13.6	1.2
East Pier	95	17.1	7.3 x 20.3	1.2 (locally 1.0 to 1.8)
West Pier	95	17.1	7.3 x 20.3	1.2 (locally 1.0 to 1.8)
West Abutment	22	33.5	2.3 x 13.6	1.1 to 1.2

The foundation treatment and design pile capacity were selected on the basis of pile load tests carried out during construction:

- Initially, load tests were conducted on piles of varying lengths driven into the untreated clay and underlying silt. The ultimate load capacities achieved by the load tests are summarized in Table 6.2.

Table 6.2 – Results of Previous Load Tests on Untreated Piles

Foundation Unit	Pile Length (m)	Days after Installation	Ultimate Load (kN)	Remarks
East Abutment	33.5	40	265	
East Pier	16.5	7	355	
	20.7	8	310	
	33.5	41	220	
West Pier	33.5	37	355	
	42.1	6	355	
	50.6	5	135-180	
West Abutment	33.5	8	620	
	33.5	54	755	Maximum applied load

- As indicated in the table, the ultimate capacities at the east abutment, east pier and west pier ranged from about 135 to 355 kN, and did not achieve the required capacity of 350 kN derived by static analysis and specified by the original foundation design. In addition, the pile capacities typically decreased as a result of artesian pressures as the piles were driven deeper into the silt. The piles at the west abutment were judged to have sufficient capacity.
- In response to the load test results, electro-osmotic treatment of the foundation soils was carried out in an effort to increase the pile capacity at the east abutment, east pier and west pier, reduce the potential for foundation settlement, and avoid the need for redesign of the foundation system. A pile length of 16.5 m was selected to prevent penetration into the underlying silt deposit. The piles at the west abutment did not warrant electro-osmotic treatment.

- During electro-osmotic treatment, static pile load testing was carried out on a selected pile (Pile E-16) at the east pier. The load test results indicated an increase in ultimate pile capacity from about 300 kN for the untreated pile to over 600 kN for the treated pile. Subsequent load testing on another pile (Pile G-5) at the treated east pier indicated an ultimate capacity in the order of 500 to 600 kN. Testing of a pile (Pile E-2) at the west pier after foundation treatment indicated that the pile did not fail under the maximum applied load of 800 kN.
- Following these load tests, a design pile capacity of 135 kN per pile was adopted for design, even after improvement of the foundation soils by electro-osmotic treatment. The design capacity was likely selected based on application of a safety factor to the measured post-treatment capacity and considerations for limiting settlement of the entire pile group.

Subsequent to bridge construction, static pile load tests have been carried out by MTO on Pile G-5 at the east pier and Pile E-2 at the west pier at various times, most recently in 1992. These tests have indicated that the piles sustained the post-treatment capacity over a period of 33 years between 1959 and 1992.

6.2 Proposed Bridge Rehabilitation

Rehabilitation of the bridge, including replacement of the bridge deck, is now planned. MTO's Bridge Office has indicated that the rehabilitated bridge with a new, heavier deck will require geotechnical resistances of up to 350 kN/pile at factored ULS and 250 kN/pile at SLS to support the new loads including transient loads. The SLS loading represents an 85% increase in pile load.

In light of this requirement, MTO retained Thurber to carry out static pile load tests on three piles at the piers to confirm that the ultimate capacities are being maintained, assess the current pile capacity, and evaluate the load-displacement behaviour of the test piles. A program of piezocone and vane shear testing was also undertaken to further evaluate the condition of the foundation clay subjected to electro-osmotic treatment, the existing foundation loading, and any aging effects during the 50 years since construction.

On the basis of the findings, analyses were carried out to evaluate the geotechnical resistance of each group of existing piles and assess the load-settlement behaviour of the foundations at each pier and abutment. Settlement estimates for selected foundation loads are provided to enable the structural designers to select loading levels that limit total settlements and differential settlements between adjacent foundation units to tolerable levels for the structure.

7 ASSESSMENT OF STATIC PILE LOAD TESTS ON SINGLE PILES

The factual results of the static pile load tests carried out on Pile G-5 and Pile E-16 at the east pier and Pile E-2 at the west pier were presented in Section 4.2 and the load-settlement plots are provided in Appendix D. The ultimate capacity of Piles G-5 and E-16 from the east pier ranged from about 550 to 600 kPa. Pile E-2 at the west pier did not reach failure at a loading of 900 kN.

The ultimate capacities of the piles tested during the current program are consistent with the capacities determined during the historical load tests on the same piles. As noted above, the ultimate capacities previously determined for the treated piles at the east pier (Piles E-16 and G-5) were in the order of 500 to 600 kN, and the pile at the west pier (Pile E-2) did not fail under the maximum load of 800 kN applied during the historical tests.

Figures showing the load-settlement curves from the current load tests plotted against the load-settlement curves previously presented in the Milligan paper (Reference 4) are provided in Appendix F. The results indicate that the ultimate pile capacities of all three piles have been maintained, and actually appear to have increased for Piles G-5 and E-2.

Based on the results of the pile load tests, an ultimate capacity of 600 kN per pile may be assumed for a single pile within the east and west pier pile groups. The factored geotechnical resistance at ULS per pile is therefore in the order of 360 kN (600 kN x resistance factor of 0.6). Based on the load-settlement curve, the immediate settlement of a single pile subjected to the maximum design load of 250 kN at SLS will be in the order of 1 to 2 mm.

The load test results indicate that single piles at the piers can accommodate the maximum design loads of 350 kN at factored ULS and 250 kN at SLS. It should be noted, however, that these conclusions are drawn from load tests on single piles whereas the foundation elements consist of pile groups comprising 22 to 95 piles. The settlement behaviour of a pile group is different from the settlement behaviour of a single pile, and evaluation of the potential settlement of the entire pile group must be considered. Assessment of the pile group behaviour is provided in Section 9.

It is further noted that static pile load tests were carried out at the piers only, and similar testing was not conducted at the abutments. Previous data indicates that the pile capacity at the west abutment exceeds that at the piers, and that conditions at the east abutment are similar to those at the east pier. The current testing program however does not provide confirmation of this assessment.

8 PIEZOCONE AND VANE SHEAR TESTS

The results of the current piezocone testing and vane shear strength tests conducted in the treated foundation soils within the pile group are provided in Appendix E. A brief description of the factual data was presented in Section 4.3.

The undrained shear strength and preconsolidation pressure profiles with depth, derived from the factual data, are presented in Appendix F. Similar profiles derived from the data previously obtained

in the untreated soils along the preliminary detour alignment (Appendix B) are also presented for comparison. The following observations are made from these figures:

1. At the east pier, the undrained shear strength of the treated clay is in the order of 50 kPa between approximate Elevation 181 to 179, and increases to about 70 kPa between Elevation 179 and 176. In the untreated clay, the undrained shear strength varies from about 20 to 30 kPa between Elevation 181 and 179, and from 30 to 50 kPa between Elevation 179 and 176.
2. At the west pier, the undrained shear strength of the treated clay varies from about 50 to 70 kPa between approximate Elevation 182 and 187. At this same level in the untreated clay, the undrained shear strength varies from about 25 to 50 kPa.
3. The above results indicate that the electro-osmotic treatment and extended period of loading from the existing bridge foundations have resulted in an increase in shear strength of the foundation clay under the pile caps.
4. The preconsolidation pressure profiles derived from the piezocone tests indicate little change in preconsolidation pressure due to the electro-osmotic treatment. At the east pier, the preconsolidation pressure of both the treated and untreated clay deposit increases from 150 to 300 kPa with depth. At the west pier, the preconsolidation pressure increases from about 200 to 300 kPa within the zone investigated during the current piezocone testing.
5. No difference in the shear strength and preconsolidation pressure profiles is evident between the piezocone pushed adjacent to the pile (CPT13-F10-01) and the piezocone pushed presumably outside the zone of electro-osmotic treatment (CPT13-F10-02) at the east pier. This appears to indicate that the entire block of clay within the pile group has experienced an increase in strength from the electro-osmotic treatment and extended period of pile loading.

9 GEOTECHNICAL RESISTANCE AND SETTLEMENT OF PILE GROUPS

The geotechnical resistance and settlement characteristics of a single pile were evaluated from the results of the static pile load tests as discussed in Section 7. The resistance and settlement of the entire pile group must also be considered when assessing the capability of the existing foundation system to carry the new deck loads. Comments regarding assessment of the pile group are presented below.

9.1 Geotechnical Resistance of Pile Groups at ULS

The geotechnical resistance of the pile group in clay will equal the lesser of the sum of the resistance of the individual piles or the resistance of the pile group acting as a block with dimensions of the entire group. Assessment of the pile group resistance for block-failure mode has indicated that the block-failure mode will not govern design.

In light of this assessment and noting that the typical centre to centre pile spacing of 1.2 m is nearly four times the pile width, the factored ULS resistance of the pile group may be computed as the sum of the factored geotechnical resistance of individual piles at ULS. Assuming a factored geotechnical resistance of 360 kN/pile at ULS as indicated by the load tests, the factored resistance at ULS of each foundation element will be as follows:

Table 9.1 – Factored Geotechnical Resistance of Pile Groups

Foundation Unit	Number of Piles	Factored Geotechnical Resistance at ULS (kN)
East Abutment	33	11,880
East Pier	95	34,200
West Pier	95	34,200
West Abutment	22	7,920

The resistance values presented in Table 9.1 reflect the ultimate capacity of the pile groups and do not consider the serviceability (settlement) of the structure under these loads. It is anticipated that the design of the rehabilitation works will be governed by the SLS condition (elastic, consolidation and creep-type settlements) of the pile groups as discussed in the next section.

With regard to the lateral resistance of the existing piles, the maximum lateral resistance per pile should be assumed to be 120 kN at factored ULS and 35 kN at SLS.

9.2 Settlement of Pile Groups at SLS

Estimates of the settlement to be anticipated under various foundation loads are required by the bridge designer to select pile loads and modify the bridge rehabilitation design as required to limit both total settlement and differential settlements between adjacent foundation elements to tolerable levels.

In order to estimate the settlement of the existing pile foundations under the increased loads applied by bridge rehabilitation, interpretation of the pile load tests, CPT and vane shear test data was carried out. This data, along with the results of oedometer tests conducted on untreated clay foundation soils during the original bridge investigation, were used to estimate the settlement of the pile groups.

The total anticipated settlement of the bridge foundations will include both immediate (elastic) settlement of the pile groups as the load is applied as well as post-construction consolidation and creep-type settlement in the clay. The approach used to compute these settlements were as follows:

1. The immediate settlement of a single pile experiencing undrained deformation under an applied load was estimated using the approximate analytical solution proposed by Randolph and Wroth (1978). This method assumes a uniform shear stress distribution along the pile shaft and considers the load sustained by the pile shaft and pile base separately. The elastic parameters used in the solution were calibrated using the initial linear elastic portion of the load-settlement curves produced during the current pile load tests.

Immediate settlement of the pile group was estimated based on the settlement of a single pile and application of the interaction factor method described by Poulos and Davis (1980) combined with diffraction factors developed by Mylonakis and Gazetas (1998).

2. Consolidation settlement of the pile group due to dissipation of excess pore pressures in the foundation soils was estimated using the equivalent raft method suggested by Tomlinson (1986). Compressibility parameters of the clay deposit were assessed from the original foundation investigation (Reference 1). In-situ stress states of the clay deposit and elastic properties of the underlying silt deposit were derived based on correlations with the CPTu tests conducted near the pile groups.
3. Long-term creep settlements were estimated for selected loads and periods of 25, 50 and 75 years using the experiment-based approach suggested by Edil and Mochtar (1988) in conjunction with the ultimate load capacity of single piles assessed from the pile load tests. Creep coefficients used in the calculation were calibrated using the observed settlement response reported during the first 30 years after bridge construction (Reference 4).

The immediate settlements and the long-term settlements estimated at time intervals of 25, 50 and 75 years following bridge rehabilitation are presented in Tables 9.2 to 9.5 for applied bridge loads of 175, 200, 225 and 250 kN per pile.

Table 9.2 – Estimated Settlement of Pile Group at West Abutment

Applied Load (kN)		Estimated Settlement (mm)			
		Immediate	Post-Construction		
Per Pile	Total Group		25 Years	50 Years	75 Years
175	3,850	1	10	15	19
200	4,400	2	14	19	24
225	4,950	3	17	23	28
250	5,500	4	21	28	34

Table 9.3 – Estimated Settlement of Pile Group at West Pier

Applied Load (kN)		Estimated Settlement (mm)			
		Immediate	Post-Construction

175	16,625	2	15	20	25
200	19,000	3	20	25	30
225	21,375	4	30	35	40
250	23,750	5	35	40	45

Table 9.4 – Estimated Settlement of Pile Group at East Pier

Applied Load (kN)		Estimated Settlement (mm)			
		Immediate	Post-Construction		
Per Pile	Total Group		25 Years	50 Years	75 Years
175	16,625	3	20	25	30
200	19,000	5	30	35	40
225	21,375	7	40	45	50
250	23,750	10	50	60	70

Table 9.5 – Estimated Settlement of Pile Group at East Abutment

Applied Load (kN)		Estimated Settlement (mm)			
		Immediate	Post-Construction		
Per Pile	Total Group		25 Years	50 Years	75 Years
175	5,775	2	16	23	28
200	6,600	3	22	30	37
225	7,425	4	28	38	45
250	8,250	6	35	46	55

The settlement estimates provided in the tables allow the bridge designer to select pile loads and modify the bridge rehabilitation design as required to limit both total settlement and differential settlements between adjacent foundation elements to tolerable levels.

Based on discussions with the MTO Bridge Office on Oct 25, 2013, it is understood that the maximum design pile loads of 350 kN at factored ULS and 250 kN at SLS include transient loading. The load requirement excluding transient loads will be less.

In view of the high predicted settlements, particularly at the east pier where the estimated total settlement is in the order of 80 mm under the 250 kN/pile loading, use of a high SLS resistance is not recommended. Considering the significant increase in bridge loads and the potential for increased settlement, it is recommended that the load increase on the existing piles be kept as low as practical, in the order of 175 to 200 kN/pile.

10 MONITORING DURING BRIDGE REHABILITATION

The foundations of the existing bridge should be monitored during and subsequent to rehabilitation of the bridge. This should include settlement monitoring of the abutment and pier pile caps and pore pressure monitoring of the foundation clay adjacent to the pile caps.

Geotechnical instruments including vibrating wire piezometers and settlement monitoring points are being installed at and near the existing bridge structure for monitoring of the existing structure during driving of the detour bridge piles. These instruments should be preserved so that they may be used for monitoring during rehabilitation of the existing bridge.

11 CONCLUSIONS

The existing Pic River Bridge is supported on pile groups consisting of steel H-piles driven into soft to stiff silty clay. During initial construction, electro-osmotic treatment was applied to the foundation soils at the east abutment, east pier and west pier to improve the pile capacity and settlement characteristics of the foundations.

Rehabilitation of the existing bridge is now planned and will include replacement of the bridge deck, resulting in a significant increase in the foundation loads. Confirmation was required that the existing piles subjected to electro-osmotic treatment have maintained the increase in pile capacity realized by treatment. Assessment of the geotechnical resistance and settlement response of the pile groups subjected to an increased loading was also required.

To provide the necessary information for rehabilitation design, a foundation investigation program consisting of static pile load tests, piezocone testing and vane shear strength testing has been carried out. Data from the foundation investigation for the original bridge, previous pile load test results, and subsurface information from an investigation carried out along a preliminary detour route has also been reviewed. Based on the results of the current investigation program and the review of existing data, the following conclusions have been drawn:

- The capacity improvements realized by electro-osmotic treatment have been maintained since original construction in 1959.
- The piezocone and vane shear strength testing indicates that the strength of the clay within the entire block of the pile group has been improved.
- Increasing the loads applied to the existing foundation system is considered feasible.
- A geotechnical resistance of 360 kN/pile at factored ULS may be employed for design. The ULS resistance of the pile group may be taken as the sum of the resistance of the individual piles.
- Based on the results of the pile load tests and computation of block settlement, estimates of settlement under various applied loads have been presented to enable the bridge designer to

select pile loads and modify the bridge rehabilitation design as required to limit both total settlement and differential settlements between adjacent foundation elements to tolerable levels.

- Considering the significant increase in bridge loads and the potential for increased settlement, it is recommended that the load increase on the existing piles be kept as low as practical, in the order of 175 to 200 kN/pile.
- Field monitoring is recommended to confirm that settlements remain within tolerable levels.

12 CLOSURE

Engineering analysis and preparation of this report were carried out by Mr. Keli Shi, P.Eng., Mr. Jason Lee, P.Eng. and Mr. Murray Anderson, P.Eng. The report was reviewed by Dr. P.K. Chatterji, P.Eng., a Designated Principal Contact for MTO Foundations Projects.

SYMBOLS, ABBREVIATIONS AND TERMS USED ON RECORDS OF BOREHOLES

1. TEXTURAL CLASSIFICATION OF SOILS

CLASSIFICATION	PARTICLE SIZE	VISUAL IDENTIFICATION
Boulders	Greater than 200mm	same
Cobbles	75 to 200mm	same
Gravel	4.75 to 75mm	5 to 75mm
Sand	0.075 to 4.75mm	Not visible particles to 5mm
Silt	0.002 to 0.075mm	Non-plastic particles, not visible to the naked eye
Clay	Less than 0.002mm	Plastic particles, not visible to the naked eye

2. COARSE GRAIN SOIL DESCRIPTION (50% greater than 0.075mm)

TERMINOLOGY	PROPORTION
Trace or Occasional	Less than 10%
Some	10 to 20%
Adjective (e.g. silty or sandy)	20 to 35%
And (e.g. sand and gravel)	35 to 50%

3. TERMS DESCRIBING CONSISTENCY (COHESIVE SOILS ONLY)

DESCRIPTIVE TERM	UNDRAINED SHEAR STRENGTH (kPa)	APPROXIMATE SPT ⁽¹⁾ 'N' VALUE
Very Soft	12 or less	Less than 2
Soft	12 to 25	2 to 4
Firm	25 to 50	4 to 8
Stiff	50 to 100	8 to 15
Very Stiff	100 to 200	15 to 30
Hard	Greater than 200	Greater than 30

NOTE: Hierarchy of Soil Strength Prediction

- 1) Laboratory Triaxial Testing
- 2) Field Insitu Vane Testing
- 3) Laboratory Vane Testing
- 4) SPT value
- 5) Pocket Penetrometer

4. TERMS DESCRIBING DENSITY (COHESIONLESS SOILS ONLY)

DESCRIPTIVE TERM	SPT "N" VALUE
Very Loose	Less than 4
Loose	4 to 10
Compact	10 to 30
Dense	30 to 50
Very Dense	Greater than 50

- (1) SPT 'N' Value Standard Penetration Test 'N' Value – refers to the number of blows from a 63.5kg hammer free falling a height of 0.76m to advance a standard 50 mm outside diameter split spoon sampler for 0.3 m depth into undisturbed ground.
- (2) DCPT Dynamic Cone Penetration Test – Continuous penetration of a 50 mm outside diameter, 60° conical steel point attached to "A" size rods driven by a 63.5 kg hammer free falling a height of 0.76 m. The resistance to cone penetration is the number of hammer blows required for each 0.3 m advance of the conical point into undisturbed ground.

UNIFIED SOILS CLASSIFICATION

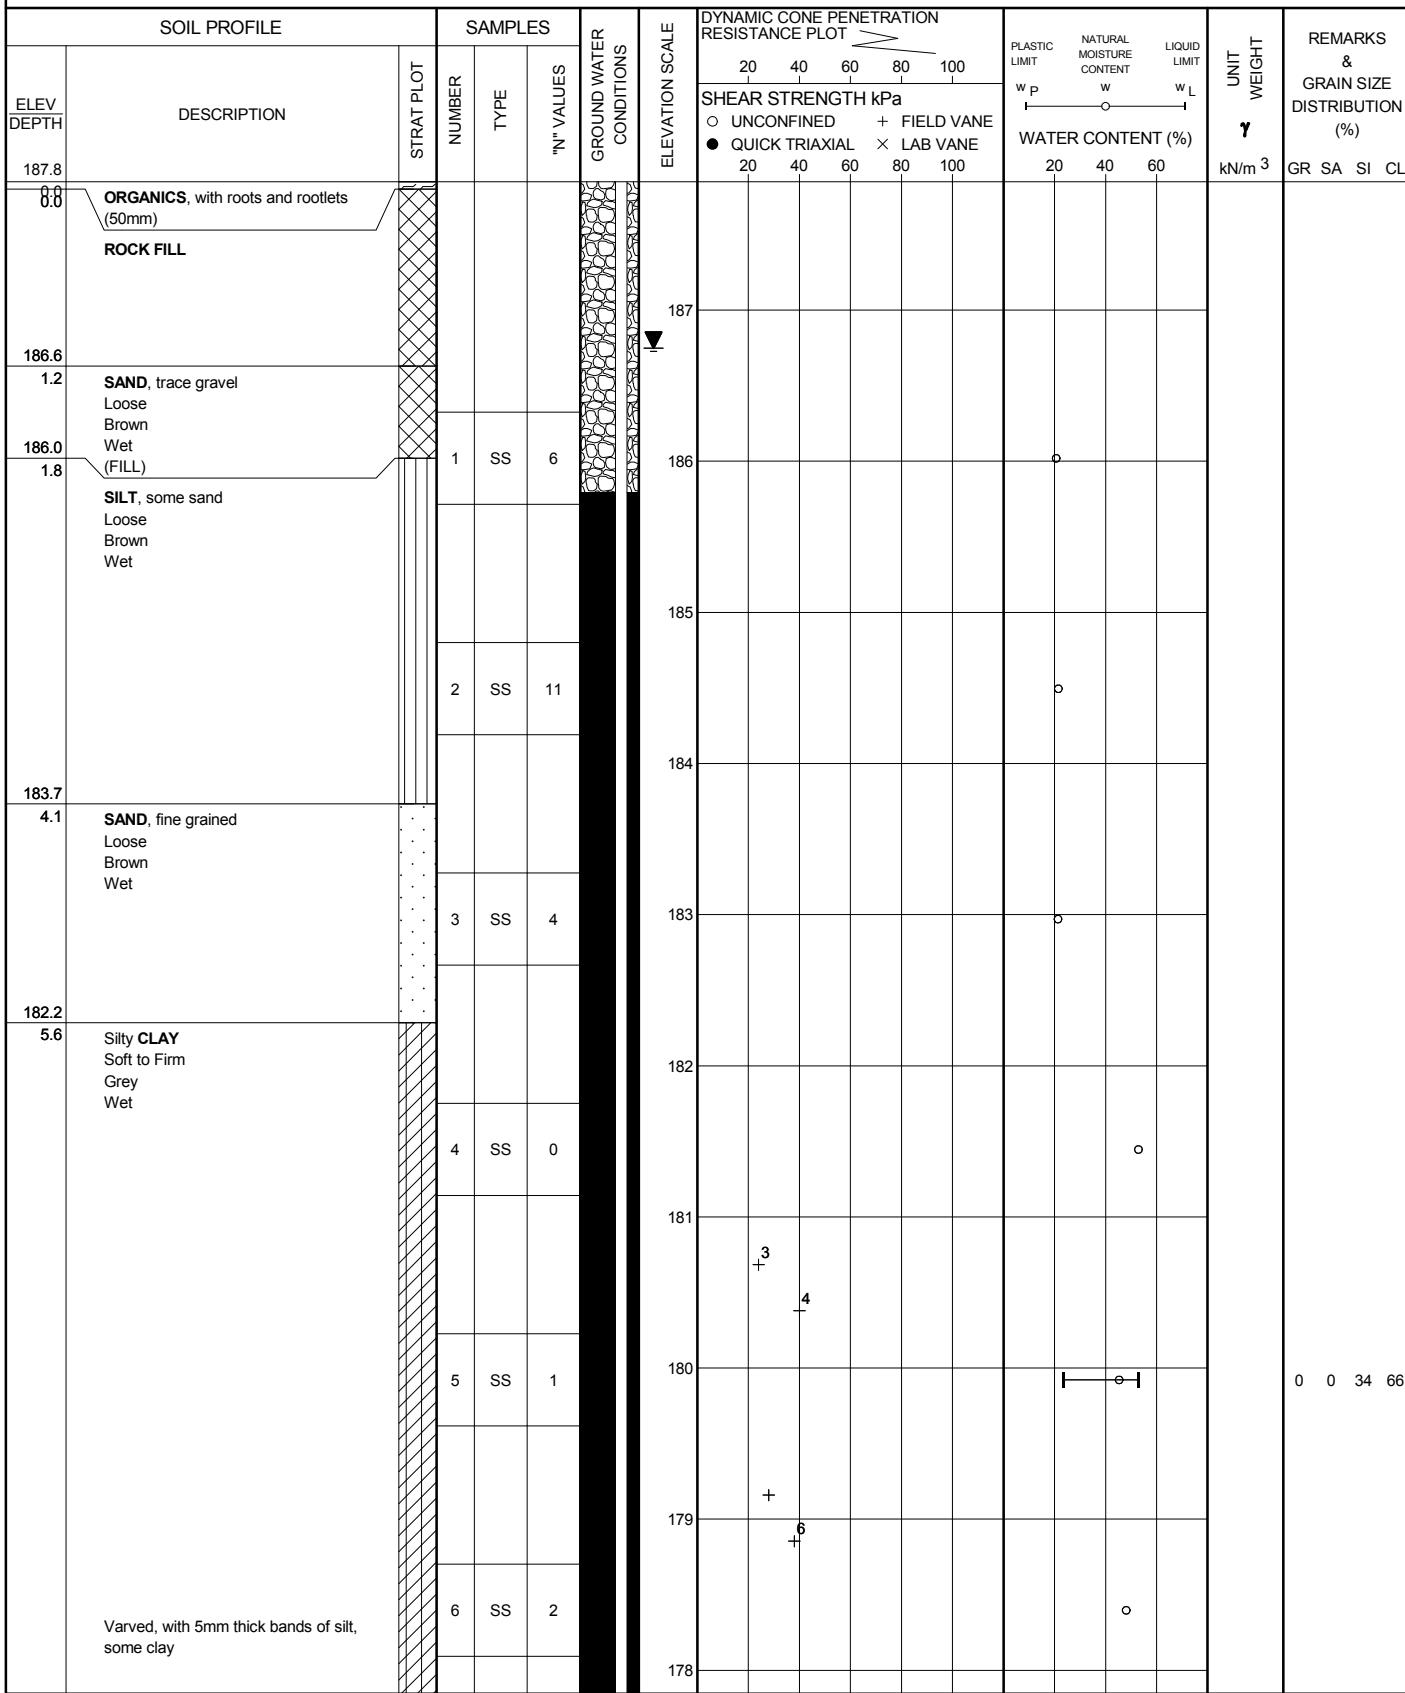

MAJOR DIVISIONS	GROUP SYMBOL	TYPICAL DESCRIPTION	
COARSE GRAINED SOILS	GRAVEL AND GRAVELLY SOILS	GW	Well-graded gravels or gravel-sand mixtures, little or no fines.
		GP	Poorly-graded gravels or gravel-sand mixtures, little or no fines.
		GM	Silty gravels, gravel-sand-silt mixtures.
		GC	Clayey gravels, gravel-sand-clay mixtures.
	SAND AND SANDY SOILS	SW	Well-graded sands or gravelly sands, little or no fines.
		SP	Poorly-graded sands or gravelly sands, little or no fines.
		SM	Silty sands, sand-silt mixtures.
		SC	Clayey sands, sand-clay mixtures.
	FINE GRAINED SOILS	ML	Inorganic silts and very fine sands, rock flour, silty or clayey fine sands or clayey silts with slight plasticity.
		CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays. ($W_L < 30\%$).
		CI	Inorganic clays of medium plasticity, silty clays. ($30\% < W_L < 50\%$).
		OL	Organic silts and organic silty-clays of low plasticity.
HIGHLY ORGANIC SOILS	SILTS AND CLAYS $W_L < 50\%$	MH	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts.
		CH	Inorganic clays of high plasticity, fat clays.
		OH	Organic clays of medium to high plasticity, organic silts.
	Pt		Peat and other highly organic soils.

PIC RIVER BRIDGE PILE LOAD TEST, CPT, AND VANE TEST LOCATION PLAN

JOB# 15-64-29

THURBER ENGINEERING LTD.

ENGINEER:	DRAWN:	APPROVED:
MEF	MFA	PKC
DATE:	SCALE:	DRAWING NO.
OCTOBER 2013	NTS	15-64-29-1

PILE TESTING UNDER STATIC AXIAL COMPRESSIVE LOAD

3 load tests will be carried out at the following pile locations:

- West Pier – Pile E2
- East Pier – Piles G5 & E16.

A Pile location sketch is attached.

PROCEDURES

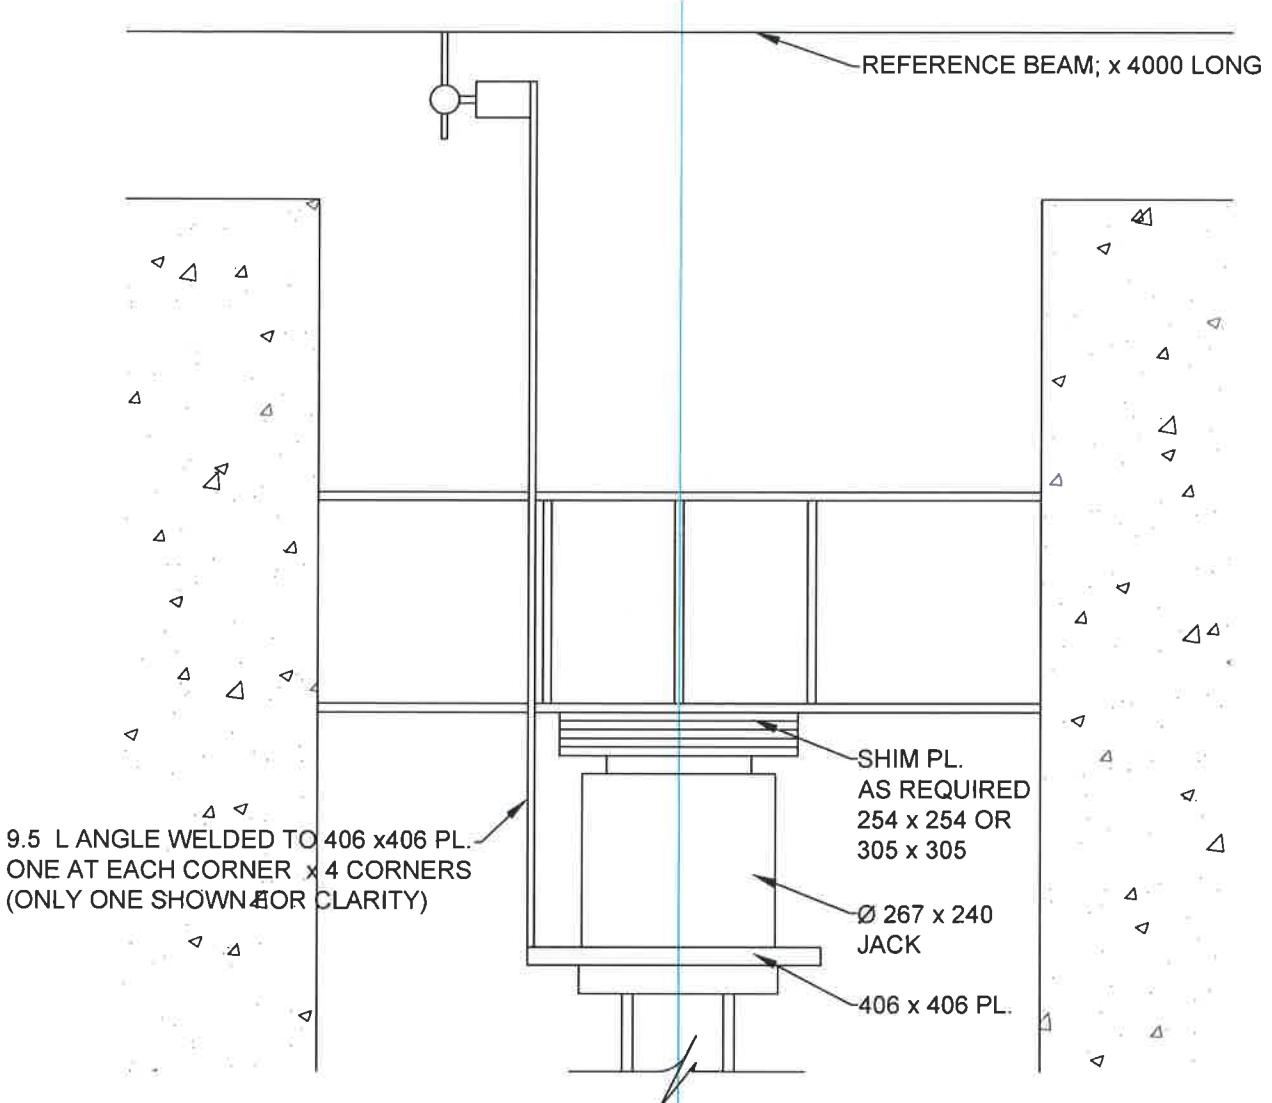

1. ASTM Standard D1143-07 applies to pile compression testing.
 - a. A jack with a load capacity of 1000kN will be provided by the Testing Contractor
 - b. 4 dial gauges will be provided for each load test setup
2. Conduct test with load increment up to a maximum load of 800 kN or until failure occurs as identified below in kN:
45, 90, 135, 180, 240, 300, 375, 450, 525, 600, 800
3. Convert loads to equivalent jack pressures using test jack calibration curve.
4. Conduct specified pile load test, measuring an accuracy of 0.01 mm with respect to an independent fixed reference system.

AXIAL COMPRESSION TEST

1. The test shall be conducted by incrementally loading and unloading until the pile fails, with measurement recorded at intervals directed by the Engineer in the Field.
 - a. Loading; as specified in the procedures above.
 - b. Unloading; Maximum 25% reduction at peak ... to 0.
2. Apply load as per identified load increments tabulated above, maintaining the load until the rate of settlement for that constant load is ≤ 0.25 mm/hr (0.01"/hr). However, maximum time period is 2 hours.
3. Obtain reading for each incremental loading at times outlined on Record sheets:
ie. 5 min., 10 min., 15 min., 30 min., 1 hr., 2 hr.
If the settlement rate is ≤ 0.25 mm/hr (0.01"/hr) at a minimum of 30 min., proceed to next load increment
4. The maximum load is 800 kN. If this force is achieved, obtain readings at the following time intervals.
ie. 5 min., 10 min., 15 min., 30 min., 1 hr., 2 hr., ... every hour thereafter.

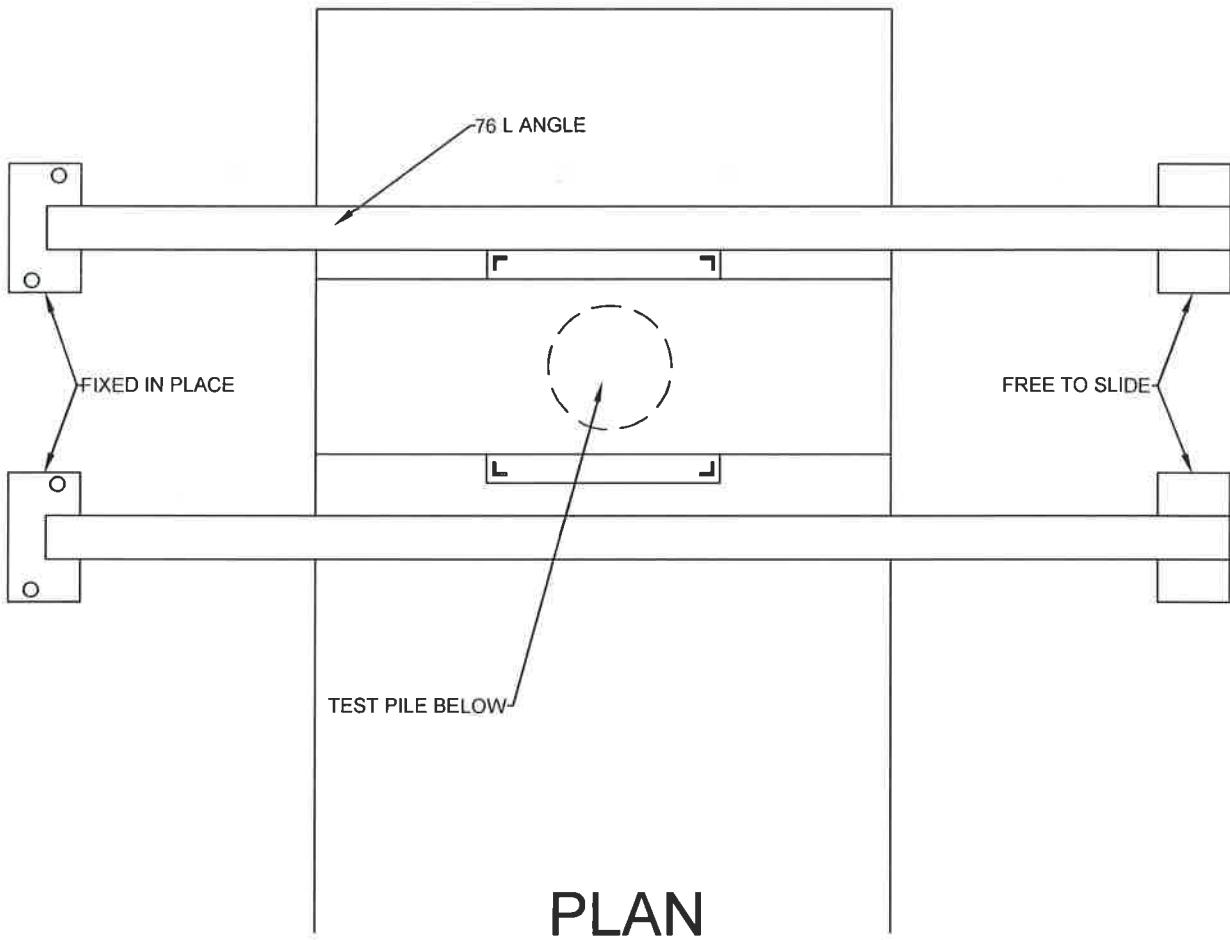

The minimum load application time is 12 hrs.; maximum 24 hours. The minimum is defined by the settlement rate ≤ 0.25 mm/hr (0.01"/hr) at 1 hour intervals

5. If failure occurs prior to 800 kN, monitor load-settlement until total settlement for the particular load is 50 mm (15% deflection of pile diameter or diagonal dimension).
6. Unloading with 25% reduction from the peak value and maintain pressure a minimum of 30 min. and maximum 1 hr. with total time less than 4 hours.
