INTRODUCTION

AA Tech Scientific Inc. (ASI) was retained by Dufresne Piling Company (1967) Ltd. (Dufresne), a part of Tomlinson Group, to perform a static and dynamic loading tests on existing piles at the demolished Pier 1 of the 3rd Line Bridge over HWY 401 in Bainsville, ON. This report presents the factual results of a compression test performed on Pile TP 2 at this site. The test was performed over two visits on 8th and 20th of August 2018.

The objective of this test was to verify capacity of the pile which was installed in 1961, based on available documents. The maximum test load, as provided by MTO specifications, is 2,000 kN.

The testing and the interpretation provided in this report are in accordance with ASTM Standard D1143-07(14), Maintained test.

SITE CHARACTERISTICS

As per the geotechnical report by Thurber Engineering Ltd. dated September 2017, the site below Pier 1 consists of about 6 m to 8 m of soft to stiff silty clay followed by about 4 to 5 m of compact to dense sandy till down to limestone bedrock where the piles are seated.

PILE LAYOUT AND TEST SETUP

The test pile was identified as an HP310x79 steel section and is located at the center of the north pile bend. The total length of the pile was about 12.6 m, as verified by ASI during pile extraction, with about 12.4 m below the underside of the cap (excavated grade) at the time of testing. The test pile was loaded against a reaction system, initially connected to two existing piles at the east and west extremities of the pier. A first test on August 8, 2018 was terminated prematurely as the welded brackets were shearing off the top of the web of the reaction piles. At the same time, the early results of the partial loading test suggested that the reaction piles would not have enough pullout resistance to complete the test. Therefore, additional reaction was proposed using dowels epoxied into the concrete cap near the reaction piles for the second test. The dowels were connected to the reaction frame with sufficient slack to allow for them to be loaded only after the reaction piles are fully engaged. Details on the reaction setup can be found in ASI's design drawings dated August 13, 2018, enclosed in Appendix 1. A photo of the actual test setup is shown in Figure 1.

One 200-tonne ASI hydraulic jack was used to apply the load. One Geokon (model 3000) resistive load cell and Novotechnik TRS electronic displacement transducers were used to control and monitor the test while sampled simultaneously by a specialized datalogger. Two displacement transducers were installed at opposite sides of the pile to monitor pile head movement against a reference beam and one transducer was placed on each reaction pile to monitor their performance. The pile and test layout are illustrated in Figure 2.

Data was collected simultaneously at 10-second intervals throughout most of the test. A lower collection rate was used through periods of long-duration sustained loading. A copy of the complete data is enclosed in Appendix 2.

Figure 1. Pile, instrumentation, and reaction system

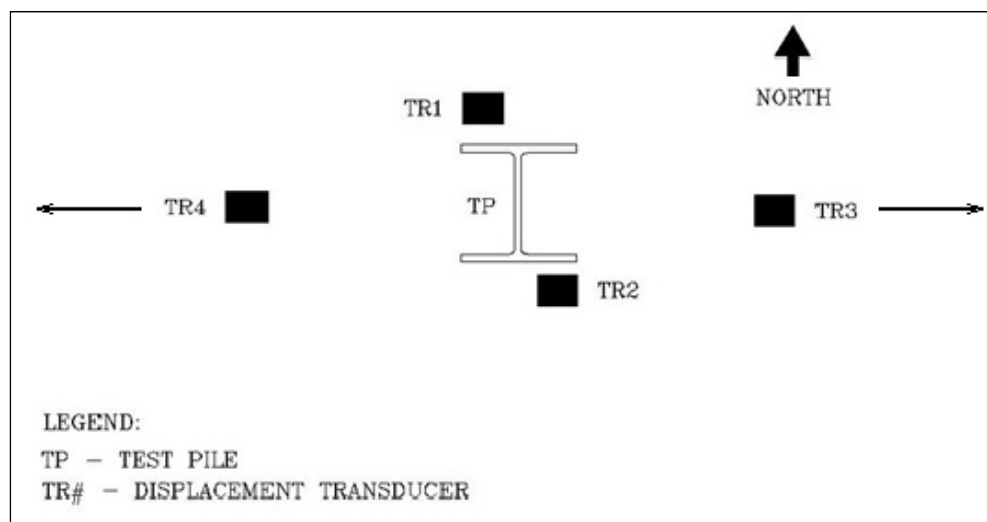

Figure 2. Pile and test layout (not to scale)

TEST RESULTS

The load was applied in increments of 250 kN, per ASTM, Procedure B (maintained test). Each increment was sustained between 20 minutes and 120 minutes, depending on the rate of pile head movement, and the maximum load was sustained for the balance of 12 hours of test duration where the movement rate threshold of 0.25 mm/h was not exceeded. The pile was unloaded in four equal decrements sustained for 60 minutes each.

Graphical results of both the initial partial test and the final test (first and second tests) are shown as load vs. average displacement in Figure 3 and Figure 4 shows the measurements from all displacement transducers including those at the reaction piles. Despite the backup connection to the pier block, the eastern reaction pile started pulling out excessively near the end of the loading cycle (see Figure 4), and became unsustainable just before reaching the 2,000 kN load. As can be seen in Figure 3, the applied load had to be dropped to about 1,900 kN to maintain it. It was apparent from later inspection that the concrete cap had cracked and was breaking free from the edge piles while lifting up with the reaction pile. The test was successfully sustained around 1,850 kN to 1,900 kN for the remainder of the test duration.

Load vs. Displacement - Pile TP2

Figure 3: Load vs. averaged pile head movement (first and second tests)

Figure 4: Load vs. pile head movement (final test, both transducers), plus reaction pile movement

While the pile may offer further resistance, it can be seen in Figure 3 that the Davisson offset failure criterion was exceeded (practical serviceability criterion). This can be further accentuated when the two tests are plotted sequentially as shown in Figure 5, which is a more accurate way to represent the test results.

The data for pile head movement with time at the maximum applied load through to the unloading at the end of the test is shown in Figure 6. The data shows that the pile was stable under the applied load towards the end of the loading cycle.

A maximum pile head movement of 24.54 mm was reached at the end of the sequential loading cycle before final unloading. A residual displacement of 15.35 mm was measured at the end of the sequential testing with negligible time-dependent rebound after complete unloading.

Figure 6: Pile head movement with time while the maximum load was sustained.

CONCLUSIONS AND RECOMMENDATIONS

The test pile was loaded to about 2,000 kN; however, a load of about 1,900 kN was sustained due to excessive movement in the west side reaction support. A prior partial test that was terminated prematurely is also reported herein and the two tests are presented in a sequential fashion to account for the entire loading history.

The data for pile head movement with time at the maximum applied load shows that the pile was stable under the applied load towards the end of the loading cycle. While the pile may be capable of sustaining higher loads, Davisson offset criterion (practical serviceability criterion) was exceeded before the final load increment.

A maximum pile head movement of 24.54 mm was reached at the end of the sequential loading cycle before final unloading. A residual displacement of 15.35 mm was measured at the end of the sequential testing with negligible time-dependent rebound after complete unloading.

These results apply only to the tested pile. Extending these test results to other piles at the site is dependent on site conditions and other factors, and is beyond the scope of this report.
